10

11   **Abstract:**

12   An alternative method to modeling is proposed for determining direct normal irradiance  
13   from sun photometer measurements. Direct normal irradiance is calculated by integration of  
14   the sun photometer spectral irradiance measurements. Using pre and post calibration spectral  
15   coefficients and the extraterrestrial spectral irradiances at each filter effective wavelength,  
16   digital counts are converted into direct spectral irradiances data. Then the trapezoidal  
17   integration procedure is applied to calculate the direct normal beam. The error associated to  
18   the integration method is estimated between 6% and 2% depending if the infrared filter is for  
19   the 1240 nm or 1640 nm respectively. Validation with collocated quasi-simultaneous  
20   manually measured and with modeled direct normal irradiance shows encouraging results.  
21   Although the results are not categorically conclusive, they evidence the capabilities of the  
22   proposed method for deriving direct normal irradiance under clear sky and also for cloudy

23 conditions. Better results are expected for validations with simultaneous automatic direct  
24 normal irradiance measurements.

25

26 Key Words: solar radiation, sun photometer, AERONET

## 27 **1 Introduction:**

28 New satellite missions allowed an accurate quantification of the earth global radiation budget.  
29 In contrast, the energy flows inside the climate system and at the earth surface is much less  
30 known, because satellites have not the capability to measure those flows directly (Wild et al.,  
31 2103). Then, up to the present and in the foreseen future, the instruments located at the  
32 surface provide the most accurate measurements of the radiation budget at that level. In that  
33 sense over the years, surface networks of solar radiation instruments have been organized  
34 worldwide. For example the Baseline Surface Radiation Network (BSRN) (Ohmura, et al.,  
35 1998) and the Solar Radiation Network (SolRad-Net) (García et al., 2008; [http://solrad-](http://solrad-net.gsfc.nasa.gov/)  
36 [.gov/](http://solrad-net.gsfc.nasa.gov/)).

37 In particular, SolRad-Net conducts high-frequency total solar flux measurements (305 – 2800  
38 nm) in quasi-real time at several of the Aerosol Robotic NETwork (AERONET) sites, to  
39 whom it is associated. Global irradiance measurements from SolRad-Net has been used to  
40 validate the AERONET estimates of the radiative forcing and forcing efficiency for variable  
41 loading conditions and different aerosol types. Results show a good agreement between the  
42 AERONET retrievals and ground based measurements of solar fluxes (García et al., 2008).  
43 But SolRad-Net lacks direct solar irradiance measurements, considered among the basics  
44 measurements by the BSRN (Ohmura et al., 1998).

45 The use of numerical models to estimate the solar irradiance and in particular the direct  
46 normal irradiance (DNI) dates back to the seventies of the XX century (ex. Bird and  
47 Hulstrom, 1981). Notable improvements have been reached but still many studies address  
48 this issue, ex. Geymard and Ruiz-Arias, (2015) and references cited in this paper.

49 The lack of DNI measurements at AERONET and SolRad-Net sites have been compensated  
50 up to the present by DNI modeling (García et al., 2008). We have implemented an alternative  
51 method for the DNI determination, consisting in the integration of the spectral direct solar  
52 radiation measurements conducted by a sun photometer (Wobrock and Eiden, 1988; García  
53 et al., 2014). Because the method relay on spectral DNI measurements it could be either a  
54 complement or an alternative to the DNI modeling.

55 In the next section, we describe the datasets used in this study and the methods applied for  
56 measuring, integrating and modeling the DNI. Also the radiative transfer code used for  
57 modeling and validating the DNI is described. Following a comparison between integrated,  
58 modeled and measured DNI values at Camagüey, Cuba, is shown and the results are  
59 discussed.

60

## 61 **2 Materials and Methods:**

### 62 **2.1 Dataset and calculation of the spectral direct irradiance.**

63 A Cooperation Agreement between the Grupo de Óptica Atmosférica, Universidad de  
64 Valladolid, Spain (GOA-UVA) and the Centro Meteorológico Provincial de Camagüey,  
65 Instituto de Meteorología, Cuba (CMPC-INSMET) was signed on 2007. GOA-UVA  
66 manages the Red Ibérica de Mediciones de Aerosoles (RIMA) that they created in 2004.  
67 Product of the cited agreement on October 2008 a sun photometer was installed at CMPC-

68 INSMET, under the Grupo de Óptica Atmosférica de Camagüey (GOAC) supervision and  
69 maintenance at 21.422°N and 77.850°W. Measurements continue up to the present, and they  
70 have been contributed to RIMA and in addition to AERONET (Antuña et al., 2012).

71 Six sun photometers operated between 2008 and 2014 at GOAC's experimental site. Two  
72 different configurations of the infrared filters have been present; two sun photometers had a  
73 1240 nm filter and the other four had a 1640 nm filter. Table 1 shows the operation periods,  
74 the nominal and effective wavelengths of the filters for each instrument and the two infrared  
75 filters configurations. The effect of the different configurations on the calculation of the  
76 DNIs will be discussed below.

77 Each sun photometer is pre and post calibrated. The procedure consist in the determination  
78 of the calibration coefficients needed to convert the instrument output digital number to a  
79 desired output, in our case radiance ( $\text{W m}^{-2} \text{ sr } \mu\text{m}^{-1}$ ). The calibration may be conducted in a  
80 laboratory using an integrating sphere or in the field using the Langley technique or by inter  
81 comparison with reference instruments. Calibration coefficients for the sun photometers  
82 installed at Camagüey are retrieved by RIMA personnel according to the standard procedures  
83 in place by AERONET (Holben et al., 1998).

84 Extraterrestrial solar spectral irradiances ( $I_{o\lambda}$ ) at the effective wavelength of each filter were  
85 integrated using the equation:

$$I_{o\lambda} = I_{cs\lambda} * e_o \quad (1)$$

86

87  $I_{cs\lambda}$  is the extraterrestrial irradiance from the solar spectrum parameterization (Gueymard,  
88 2004) and  $e_o$  is the solar eccentricity is defined as the mean Sun-Earth distance (1AU) divided  
89 by the actual Sun-Earth distance squared (Kumar and Umanad, 2005) derived according the

90 equation:

$$e_0 = 1 + 0.033 * \cos\left(\frac{2\pi nd}{365}\right) \quad (2)$$

91  $nd$  is the number of order of the day in the year.

92 For each sun photometer at each effective wavelength, the rates of the  $I_{0\lambda}$  value to the pre and  
93 post calibration coefficients were integrated. Those are the conversion coefficients for  
94 converting the digital counts into spectral direct irradiance values. Then values of the  
95 conversion coefficients for all the days between the pre and post calibration dates were  
96 derived by linear interpolation for each one of the effective wavelengths. The former set of  
97 daily conversion coefficients at each wavelength were used to calculate the spectral direct  
98 irradiance for each observation at each effective wavelength, using the average of the sun  
99 photometer triplets' measurements.

100

101 **2.2 Integrated DNI.**

102 Trapezoidal integration method (Whittaker and Robinson, 1967) was used to integrate the  
103 spectral sun photometer measurements to obtain the integrated DNI. To cover the region of  
104 the spectrum outside the two extreme sun photometer wavelengths two additional integration  
105 points were added, one at each side. They were at the wavelengths of 300 and 2600 nm and  
106 the associated values of extraterrestrial spectral direct irradiances (Gueymard, 2004) were  
107 used in the integration. The integration intervals were defined by 9 effective wavelengths  
108 plus the two additional wavelengths added in each side; 300 and 2600 nm.

109 The constant contribution of  $55.2 \text{ W m}^{-2}$  was added to the integral integrated using the  
110 trapezoid method, to include the regions from 0.5 nm to 300 nm and from 2600 nm to 10000

111 nm. It was calculated integrating the values of each one of the extraterrestrial spectral  
112 irradiance from all the available lines in each one of the two intervals (Gueymard, 2004).  
113 The spectral intervals of integration were selected according to the spectral position of each  
114 neighbor spectral lines.  
115 For characterizing the error associated to the application of the trapezoidal method to the  
116 resolution of the sun photometer measured wavelengths, the extraterrestrial spectrum  
117 (Gueymard, 2004) was fully integrated obtaining the solar constant. Then the trapezoidal  
118 integration method was applied to the extraterrestrial spectrum, but only taking into account  
119 the intensity of spectral lines matching the 9 filters effective wavelengths and the two  
120 additional selected, 300 and 2600 nm. The two different filters configuration were taken into  
121 account, producing two different results. The comparison of the results obtained with the  
122 trapezoidal method of integration with the solar constant, considering both infrared filters  
123 configurations, shows an overestimation of 6 % and 2 % for 1240 nm and 1640 nm filters,  
124 respectively. Figure 1 illustrates the increase of the integration error in 4% in sun  
125 photometers with the 1240 nm filter respect to the ones with the 1640 nm filter. The error of  
126 the trapezoidal integration method is the area between the continuous and discontinuous lines  
127 and the curve representing the extraterrestrial spectrum. This area is higher in the case of the  
128 continuous lines connecting the 1020, 1240 and 2600 nm wavelengths than for the  
129 discontinuous line connecting 1020, 1640 and 2600 nm.  
130 Only sun photometer measurements from AERONET Version 2 Direct Sun Algorithm  
131 (DSA) products were used in the present study to guarantee the cloud free conditions in the  
132 line of sight of the instrument and quality-assured observations (Holben et al., 1998; Smirnov  
133 et al., 2000).

134

135 **2.3 DNI measurements at Camagüey site.**

136 Hourly measured DNI from the Camagüey meteorological station, located less than 100 m  
137 from the sun photometer, were selected. The site operates a Yanishevsky actinometrical  
138 station with instruments supplied in the 70s and 80s by the Hydrometeorological Service of  
139 the former Soviet Union. The Yanishevsky station consists of an actinometer, model M-3; a  
140 pyranometer, models M-80-M or M-115-M; a balanzometer model M-10-M and an analogic  
141 galvanometer, models GSA-1MA or GSA-1MB (Antuña et al., 2008). Calibrations of all the  
142 instruments are conducted periodically by comparison with a master actinometer and a  
143 master pyranometer. Trained observers conduct measurements manually, following the  
144 standard methodologies and quality control procedures established for this set of instruments  
145 (GGO, 1957). In cases of precipitation or variable cloudiness the time for conducting the  
146 actinometrical manual measurements may be extended up to minutes 10 minutes to guarantee  
147 that the solar flux remains constant during the entire measurement. (GGO, 1957; GOAC,  
148 2010). It could produce time inaccuracies in the register of the observation.

149 Once a measurement is conducted and registered in a notebook designed for that purpose, all  
150 the measurement information is digitized using the software Actino version 2.0 (Estevan,  
151 2010). This software is an update of the early versions used for the data rescue of the entire  
152 1981 to 2005 Camagüey's solar radiation dataset (Antuña et al., 2008). The current version  
153 is used operationally for quality controlling, processing and storing the measurements.  
154 Actino's outputs also feeds in real time the "Servicio de Diagnóstico de Radiación Solar para  
155 Cuba", SDRS (<http://www.goac.cu/actino/>) and the "Servicio de Diagnóstico de Espesor  
156 Óptico para Cuba", SDRS (<http://www.goac.cu/eoc/>), provided by GOAC. The software

157 includes a robust quality control of the input data, its processing and the quality control of  
158 the outputs (Antuña et al., 2011). Because of the aging process of the Soviet era instruments,  
159 the magnitude of the error associated to the broadband actinometers currently operating in  
160 Cuba is estimated around 10 %.

161

#### 162 **2.4 Modelling DNI.**

163 We used the radiative transfer code developed at the Geophysical Fluid Dynamics Laboratory  
164 from the National Oceanic and Atmospheric Administration (Ramaswamy and Freidenreich,  
165 1991; Freidenreich and Ramaswamy, 1999). Vertical profiles of the gasses mass mixing  
166 ratio are used by the code. It also includes particulate scattering and absorption, Rayleigh  
167 scattering, and gaseous absorption by O<sub>2</sub>, O<sub>3</sub>, CO<sub>2</sub>, and H<sub>2</sub>O. Single-scattering properties of  
168 clouds and aerosols are integrated into the 25 pseudo-monochromatic bands between 0 and  
169 57 600 cm<sup>-1</sup>, the solar spectrum is divided for the calculations. The δ-Eddington method is  
170 used for reflection and transmission calculus for homogeneous layers and the “doubling-  
171 adding” technique to obtain the vertical profiles of flux densities and heating rates.

172 Prescribed tropical temperature and water vapor mixing ratio profiles (McClatchey, 1972)  
173 replaced by the ones determined for Camagüey (Barja and Antuña, 2011). Those profiles  
174 were derived from the mean aerological soundings conducted from 1981 to 1988 at  
175 Camagüey site (Barja and Antuña, 2008). The values of the pressure, temperature and water  
176 vapor mixing ratio at the surface for the site were also used together with monthly mean  
177 albedo values for Camagüey (Platero et al., 2015). In addition, the sun photometer derived  
178 aerosol optical depth (AOD) at 500 nm and the corresponding solar zenith angle, from  
179 AERONET Version 2 DSA products, for the original sun photometer coincident

180 measurements, were used for DNI modeling (Holben et al., 1998; Dubovic et al., 2000).

181

182 **2.5 Coincidence criteria and cloud cover classification.**

183 The applied time coincident criteria consisted in selecting measured DNI, conducted in a  
184 time window of  $\pm$  5 minutes with respect to the integrated DNI. In case that more than one  
185 AERONET Version 2 DSA measurement matched the criteria, only the more near in time  
186 measurement was selected and the rest discarded. It was selected taking in consideration the  
187 methodology applied for the actinometrical manual measurements. They are conducted in  
188 the interval of up to 10 minutes in presence of precipitation or variable cloudiness. In the  
189 former conditions, precipitation or variable cloudiness, the extension of the measurement  
190 time pursues the goal to guarantee that the solar flux remains constant during the entire  
191 measurement. (GGO, 1957; GOAC, 2010). Modeled DNI were only determined for the set  
192 of AERONET Version 2 DSA measurements selected from the application of the coincidence  
193 criteria.

194 The set of coincident measured, integrated and modeled DNIs was classified according to  
195 following four categories of the tenths of sky cloud cover:

- 196 • Cloudiness 0 to 10 (All Sky).  
197 • Cloudiness 0 to 1 (Clear Sky)  
198 • Cloudiness 2 to 6 (Partially Cloudy)  
199 • Cloudiness 7 to 10 (Overcast)

200 The comparison was conducted between measured and integrated DNI, modeled and  
201 integrated DNI and modeled and measured DNI. For each one of those pairwise comparisons  
202 the four cloud cover categories were applied and the results depicted in the corresponding

203 scatter diagrams. In addition, least squares linear fits were conducted, determining the slope,  
204 intercept correlation coefficient ( $R$ ) and coefficient of determination ( $R^2$ ).

205

206 **3 Validating the integrated DNI.**

207 **3.1 Integrated DNI vs. measured DNI:**

208 Figure 2 shows the scatter plots of integrated vs. measured DNI for the four sky cloud cover  
209 categories. The respective least squares linear fit for each category is shown in red. Only in  
210 the clear sky condition, sky cover 0-1, the points are concentrated mainly around the least  
211 squares linear fit with a low dispersion. In the rest of the cloud cover categories, a big  
212 dispersion is present, but still a high concentration of points may be appreciated around the  
213 same region where the points are concentrated in the clear sky case, but in higher amounts.

214 In the figure 2 in general for most of the sky cloud cover categories the integrated DNI  
215 slightly overestimates the measured DNI. Table 2 reports the slopes and intercepts from the  
216 linear fits of all the combinations of comparisons between measured, integrated and modeled  
217 DNI, grouped according to the four sky cloud cover categories. The intercepts for the four  
218 sky cloud cover categories for the integrated vs. measured DNI range between -100 and 25  
219  $\text{Wm}^{-2}$ , indicating the magnitudes of the overestimations of the integrated DNI, in the case of  
220 the negative values and the opposite for the positive value in the overcast category.

221 Table 3 contains the  $R$  and  $R^2$  values derived from the linear fits of all the combinations of  
222 comparisons between measured, integrated and modeled DNI, grouped according to the four  
223 sky cloud cover categories. For the clear sky category, the  $R$ -value is 0.92, while for the rest  
224 three sky cloud cover categories  $R$  is in the order of 0.85, causing the  $R^2$  value of 0.84 for  
225 clear sky and for the rest three-sky cloud cover categories to drop to the range between 0.72

and 0.73. A comparison between modeled and measured DNI at six solar radiation stations located between 23.5 °N and 24.6 °N in the United Arab Emirates (UAE), under clear sky, reports  $R^2$  values ranging between 0.83 and 0.86 (Eissa et al., 2015). The  $R^2$  value of 0.92 under clear sky for the measured and integrated DNI is around 10% higher than the results described for the UAE solar radiation stations between measured and modeled DNI. The fact that UAE stations are automatic tropical stations in the same latitudinal band than Camagüey, allows using the described results to show the feasibility of the proposed method.

233

234 **3.2 Integrated DNI vs. Modeled DNI:**

235 The scatter plots of integrated vs. modeled DNI for the four-sky cloud cover categories are  
236 in figure 3. The dispersion seen in figure 2 decreased and also the magnitude of the  
237 intercepts, except for the overcast category, whose value in table 2 range between around -  
238 60 and 30 Wm<sup>-2</sup>. These is the same overestimation of the integrated DNI observed with  
239 respect to the measured DNI, in the present case with respect to the modeled DNI, also for  
240 all the sky cloud cover categories except for the overcast category. Note that the intercept  
241 values, are slightly lower in this case. The values of R, in table 3, for the four sky cloud cover  
242 categories are above 0.94, reaching for the clear sky category the value of 0.97, a high value.  
243 In the same table 3,  $R^2$  range between 0.88 and 0.94, the last value the one corresponding to  
244 the clear sky category. The  $R^2$  value of 0.94 for the clear sky category is well over the values  
245 reported by Eissa et al., (2015) demonstrating the potential of the proposed method. Also  
246 for the other three sky cloud cover categories the values of  $R^2$  are higher than the reported by  
247 the study conducted in the UAE.

248 The better results achieved in comparing the integrated DNI with the modeled DNI than in  
249 the case of the comparison with the measured DNI, could be attributed to the limitations of  
250 the measured DNI dataset. The aging of the actinometrical instruments dating from the  
251 Soviet era, represented in the estimated 10% magnitude of the error; the inaccuracy in the  
252 exact time the measurements are conducted and other potential issues related to manual  
253 measurements represent limitations of the dataset. For that reason, a comparison between  
254 the modeled DNI and measured DNI follows.

255

### 256 **3.3 Modeled DNI vs. measured DNI:**

257 Modeled vs. measured DNI scatter plots, on figure 4, shows a lower dispersion than the  
258 integrated vs. measured DNI plot on figure 2, but higher than the one in figure 3 for the  
259 integrated vs. modeled DNI. The magnitudes of the intercepts range between around 35 and  
260 -14 Wm<sup>-2</sup>, with the only negative value registered for the clear sky category. Values of R  
261 and R<sup>2</sup>, in table 3, are very similar to the ones for the integrated vs. measured DNI linear fits,  
262 but notably lower than the ones for the integrated vs. modeled DNI comparison  
263 The results described above are not categorically conclusive mainly for the limitations of the  
264 manual DNI measurements available to test the robustness of the proposed method. But they  
265 are encouraging. The comparison of the integrated DNI with the modeled DNI may be  
266 considered good results in general for the four sky cloud cover categories, but in particular  
267 for the clear sky. Results under cloudy conditions show indications that the method could be  
268 also valuable under these sky cover conditions. Under cloudy conditions few models has  
269 shown good performance; that is a pending issue in modeling solar radiation. Better results

270 are expected for the validation of the method in an AERONET site hosting automatic DNI  
271 measurements.

272

273 **4 Conclusions:**

274 The integrated DNI from spectral sun photometer measurements show a reasonable  
275 agreement both with manually measured DNI and with modeled DNI using a state of the art  
276 radiative transfer code, adjusted for the location both actinometrical and sun photometer  
277 measurements are conducted. Under conditions of no clouds in the line of sight of the sun  
278 photometer, the correlation and determination coefficients show good results for the  
279 comparison between integrated DNI and both measured and modeled DNI when compared  
280 to with results achieved at six tropical stations in the same latitude band. The trapezoidal  
281 integration method applied, produces an overestimation error of the integrated DNI between  
282 6% and 2% depending if the configuration of the higher wavelength infrared filter is 1240  
283 nm or 1640 nm respectively. This error is in the same order of magnitude than the error  
284 associated to the DNI measured by the manual actinometer. The lack of absolute time  
285 coincidence of automatic sun photometer measurements and manually measured DNI is an  
286 important source of error.

287 Under cloudy conditions the method show results equivalent to the ones achieved for the six  
288 tropical stations at UAE under clear sky conditions. That is promising, because few models  
289 has shown good performance under those conditions. The results are not categorically  
290 conclusive, but they show clear indications of the feasibility of the proposed method. Better  
291 results are expected when automatic measured DNI will be used for the validation.

292 At AERONET sites locations, coincident or not with SolRad-Net instruments, it would be  
293 expected that the availability of the integrated DNI would contribute to increase the interest  
294 of local host institutions for the continuous overseen operation of the sun photometers. They  
295 would become more engaged in the operation of the instruments and its maintenance with  
296 the aim to generate research quality data and at the same time additional real time solar  
297 radiation information applicable to local services and weather forecasts.

378 Tables:

379 Table 1: Operational periods of sun photometers at Camagüey, Cuba. Filters nominal and  
 380 effective wavelengths for each instrument. The two different configurations of the infrared  
 381 filters could be appreciated.

Instrument Number	Operations Period		Design Wavelengths (nm)									
	Begin	End	1640	1240	1020	935	870	675	500	440	380	340
425	2008/10/07	2009/04/10	--	1246	1020	937	870	675	498	435	380	339
353	2009/06/04	2010/04/23	--	1247	1021	934	871	674	499	438	380	339
419	2010/06/03	2011/06/17	1624	--	1021	939	869	676	502	442	379	339
424	2011/07/21	2012/07/16	1643	--	1016	934	870	673	499	435	380	339
353*	2012/07/23	2013/05/29	1646	--	1020	934	870	673	500	438	380	339
424	2013/09/30	2014/08/02	1643	--	1016	935	870	674	499	436	381	339

382  
 383 Table 2: Slopes and intercepts from the least squares linear fits of the comparisons between  
 384 measured, integrated and modeled DNI, grouped according to the four sky clouds cover  
 385 categories.

Sky Cloud Cover	integrated vs. measured DNI		integrated vs. modeled DNI		Modeled vs. Measured DNI		Cases
	Slope	Intercept	Slope	Intercept	Slope	Intercept	
All Sky	0.889	-44.7	1.034	-40.7	0.886	32.2	2382
Clear Sky	0.947	-94.1	1.078	-62.7	1.003	-14.0	185
Partially Cloudy	0.871	-53.8	1.034	-49.7	0.892	26.4	1957
Overcast	0.980	25.0	1.073	33.3	0.852	34.8	240

386

387

388

389 Table 3: Correlation and determination coefficients from the least squares linear fits of the  
390 comparisons between measured, integrated and modeled DNI, grouped according to the four  
391 sky clouds cover categories.

392

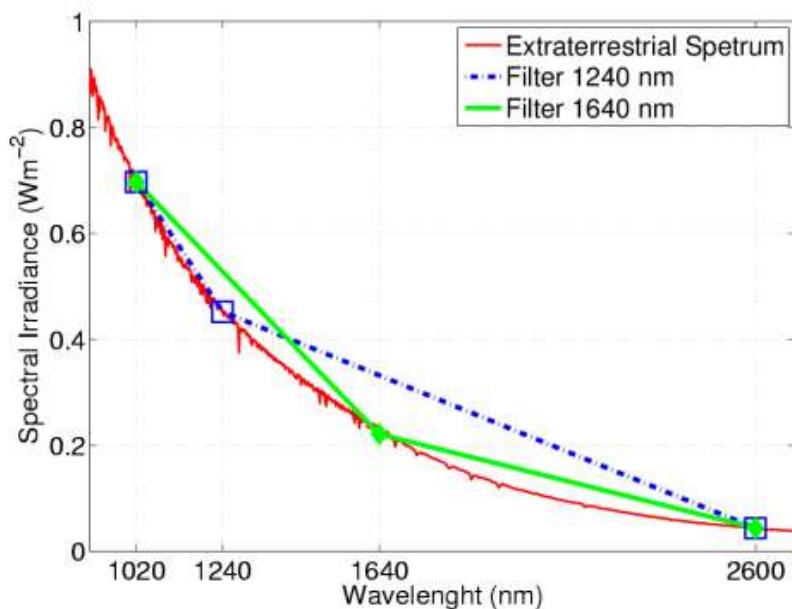

Sky Cloud Cover	Integrated vs. Measured DNI		Integrated vs. Modeled DNI		Modeled vs. Measured DNI		Cases
	R	R <sup>2</sup>	R	R <sup>2</sup>	R	R <sup>2</sup>	
All Sky	0.851	0.725	0.948	0.899	0.849	0.720	2382
Clear Sky	0.918	0.842	0.967	0.935	0.928	0.861	185
Partially Cloudy	0.846	0.716	0.953	0.907	0.846	0.716	1957
Overcast	0.855	0.730	0.940	0.884	0.857	0.734	240
