Figure S1 The MAX-DOAS instrument mounted at 5 m a.gl. (left) at Fort McKay South and the view South of the instrument.
Section 2 Additional Information on MAX-DOAS Spectral Fitting

Figure S2 Examples of spectral retrievals of SO$_2$, NO$_2$, and O$_4$. Retrieved dSCDs were $5.79(\pm 0.09)x10^{17}$ molec cm$^{-2}$, $1.2(\pm 0.01)x10^{17}$ molec cm$^{-2}$, and $3.96(\pm 0.08)x10^{43}$ molec cm$^{-2}$, respectively. The spectra were measured under clear sky conditions at 2° in 2013 at 22:37 UTC on Aug 23 and 18:34 UTC on Sep 04, respectively.
SO₂ Spectral Fitting Experiments with Calibration Gas Cell

A SO₂ gas cell with a slant column density (SCD) of 2.2e¹⁷ (+/- 10%) molecules cm⁻² was placed inside the MAX-DOAS telescope tube. Scattered solar light spectra were recorded around solar noon at viewing elevation angles of 2°, 4°, 8°, 30° and 90° above the horizon, followed by a 90° measurement without the gas cell. This second zenith measurement was used as the FRS. Active-DOAS measurements of the SO₂ gas cell confirmed the SCD. dSCDs of SO₂ were fit in DOASIS with varying fitting windows using a lower limit range of 303-318 nm and an upper limit range of 309-340 nm in ~0.3 nm increments. The fit components can be found in Table 2.

Fitting SO₂ in the measured wavelength region is challenging because the SO₂ absorption features (Fig. S3) are strongest where the measured light intensity was small, and the influence of stray light can be large. Increasing O₃ absorption at decreasing wavelengths approaching 300 nm reduces the spectral signal. The lower limit wavelength of the fitting window must balance including strong SO₂ features and enough signal intensity. The upper limit wavelength should ensure that the fitting window includes as many SO₂ absorption features as possible while excluding wavelengths where SO₂ absorption features are so weak that degrees of freedom and fitting uncertainty are increased.

dSCD of SO₂ fitted from the spectra measured at elevation angles closer to horizon-pointing exhibited fewer wavelength fitting windows where the fitted dSCD was within +/-15% of the expected value. Spectra measured at lower elevation angles had less UV signal because the longer light path lengths closer to the ground experience more Rayleigh scattering that preferentially scattered away shorter wavelengths. Since the visible light intensity remains the same and is a source of stray light, the reduced UV signal increased the impact of stray light on the dSCD (signal to noise ratio decreases). Stray light artificially increases the measured intensity and tends to cause underestimation of the retrieved dSCD.

Stray light has the largest impact on the signal at the lowest wavelengths where the measured intensity was the lowest. Stray light interference is apparent in the frequent underestimation of the dSCD for the 2° spectrum with fitting windows with lower limits <307 nm (gray datapoints in Fig. S4). The dSCDs were often >15% less than the expected value for fitting windows with a lower limit <308 nm, particularly for the lower elevation angles. The fitted dSCD was sensitive to small changes in the fitting window for lower limits <308 nm and upper limit <330 nm, changing up to ~20% change for a 0.5 nm difference in the lower limit (Figs. S4 & S5). The fitted dSCD is inversely proportion to the SO₂ absorption cross section (Fig S4). When the strongest SO₂ absorption feature included in the fit was an absorption maximum, the measured intensity in lowest wavelength region was even further reduced, leading to up to a 25% reduction in the dSCD compared to a window where the adjacent absorption minimum was the strongest feature included (Fig. S5). This result implies that small errors in the wavelength calibration or wavelength shift could significantly deviate the dSCD from the true value. dSCDs exhibited less dependence on the lower limit for windows with lower limit wavelengths of 310.4-311 nm due to increased signal intensity. For lower limit wavelengths >312 nm, the SO₂ absorption features are substantially weaker, leading to dSCDs that tended to be >15% larger than the expected value and varied significantly with relatively small changes in higher limit.
wavelength (Fig. S4). Since the SO$_2$ absorption features after 324 nm are very weak, the fitting range upper limit was set to 324 nm.

Based on these results, an SO$_2$ fitting range of 310.5-324 nm was chosen for this instrument.

Figure S3 SO$_2$ Absorption Cross Section (top) and Measured Intensity from the 2$^\text{nd}$ Spectrum from 300-320 nm (bottom).
Figure S4 dSCDs of SO2, $2.2 \times 10^{17}$ molecules cm$^{-2}$ gas cell using varying spectral fitting ranges. Gray and black datapoints indicate that the fitted dSCD was 15% less than and greater than $2.2 \times 10^{17}$ molec cm$^{-2}$, respectively.
Figure S5 Fitted dSCD of SO$_2$ with fitting window upper limit of 320 nm from 2$^\text{o}$ Spectrum using a 2.2x10$^{17}$ molec cm$^{-2}$ gas cell (black trace) and SO$_2$ absorption cross section degraded to the spectrometer’s resolution (green trace).
Figure S6 Lidar measurements of vertical profiles of aerosol extinction (middle panels) and S-ratios (bottom panels) under polluted conditions (left column) and relatively clean conditions (right column) at Oski-Ötin in 2018.
