## 7 8 **Abstract**

9 Total Column Water Vapor (TCWV) is important for the weather and climate. TCWV is  
10 derived from the Ozone Monitoring Instrument (OMI) visible spectra using the Version 4.0  
11 retrieval algorithm developed at the Smithsonian Astrophysical Observatory. The algorithm uses  
12 a retrieval window between 432.0 and 466.5 nm and includes updates to reference spectra and  
13 water vapor profiles. The retrieval window optimization results from the trade-offs among  
14 competing factors.

15 The OMI product is characterized by comparing against commonly used reference datasets –  
16 Global Positioning System (GPS) network data over land and Special Sensor Microwave Imager  
17 / Sounder (SSMIS) data over the oceans. We examine how cloud fraction and cloud top pressure  
18 affect the comparisons. The results lead us to recommend filtering OMI data with cloud fraction  
19 less than  $f = 0.05 - 0.25$  and cloud top pressure  $> 750$  mb (or stricter), in addition to the data  
20 quality flag, fitting RMS and TCWV range check. Over land, for  $f = 0.05$ , the overall mean of  
21 (OMI-GPS) is 0.32 mm with a standard deviation ( $\sigma$ ) of 5.2 mm, the smallest bias occurs when  
22  $TCWV = 10 - 20$  mm, and the best regression line corresponds to  $f = 0.25$ ; Over the oceans, for  $f$   
23  $= 0.05$ , the overall mean of (OMI-SSMIS) is 0.4 mm (1.1 mm) with  $\sigma = 6.5$  mm (6.8 mm) for  
24 January (July), the smallest bias occurs when  $TCWV = 20 - 30$  mm, and best regression line  
25 corresponds to  $f = 0.15$ . For both land and the oceans, the difference between OMI and the  
26 reference datasets is relatively large when TCWV is less than 10 mm. The bias for Version 4.0  
27 OMI TCWV is much smaller than that for Version 3.0.

28 As test applications of the Version 4.0 OMI TCWV over a range of spatial and temporal  
29 scales, we find prominent signals of the patterns associated with El Niño and La Niña, the high

30 humidity associated with a corn sweat event and the strong moisture band of an atmospheric  
31 river (AR). A data assimilation experiment demonstrates that the OMI data can help improve the  
32 Weather Research and Forecasting model (WRF)'s skill at simulating the structure and intensity  
33 of the AR and the precipitation at the AR landfall.

## 34 **1 Introduction**

35 Water vapor is of profound importance for weather and climate. Through condensation, it  
36 forms clouds that modify albedo, affect radiation and interact with particulate matter. In addition,  
37 latent heat released from water vapor condensation can influence atmospheric energy budget and  
38 circulation. Water vapor is the most abundant greenhouse gas, accounting for ~50% of the  
39 greenhouse effect (Schmidt et al., 2010). Thus, monitoring the spatial and temporal distributions  
40 of water vapor is crucial for understanding water-vapor related processes.

41 Water vapor has been measured using a variety of in situ and remote sensing techniques from  
42 the ground, air and space. Satellite data provide global perspective and are indispensable for  
43 constraining reanalysis products (Dee et al., 2011; Gelaro et al., 2017). The current satellite  
44 water vapor datasets are evaluated through the Global Energy and Water cycle Exchanges  
45 (GEWEX) Water Vapor Assessment program (Schröder et al., 2019). These datasets are derived  
46 from visible, near infrared (NIR), Infrared (IR), microwave and Global Positioning System  
47 (GPS) measurements. Each dataset has its own characteristics and contributes to the  
48 understanding of water vapor in its own way. For example, microwave data are useful for both  
49 clear-sky and cloudy-sky conditions, but are best suited for non-precipitating ice-free oceans due  
50 to the complications associated with land surface emissivity; NIR data are best suited for the  
51 land, as the surface albedo is low over the oceans; IR data are available over all surface types,  
52 but are strongly influenced by clouds and less sensitive to the planetary boundary layer; visible  
53 data are sensitive to the boundary layer over both land and the oceans, but are complicated by  
54 uncertainties in clouds and aerosols (Wagner et al., 2013).

55 Total Column Water Vapor (TCWV, also called Integrated Water Vapor - IWV, or  
56 Precipitable Water Vapor - PWV) can be retrieved from the 7v water vapor vibrational polyad  
57 band (around 442 nm) despite the weak absorption (Wagner et al., 2013). This made it possible  
58 to derive TCWV from instruments measuring in the blue wavelength range. Since water vapor is  
59 a weak absorber here, saturation of spectral lines is not of concern (Noël et al., 1999). Moreover,

60 the similarity between the land and ocean surface albedo in the blue wavelength range suggests a  
61 roughly uniform sensitivity of the measurement over the globe (Wagner et al., 2013). However,  
62 weaker absorption tends to result in larger relative uncertainties, especially for low TCWV  
63 amount.

64 Using the visible spectra measured by the Ozone Monitoring Instrument (OMI), Wang et al.  
65 (2014) retrieved Version 1.0 TCWV from 430 – 480 nm and publically released the data on the  
66 Aura Validation Data Center (AVDC, <https://avdc.gsfc.nasa.gov>). Wang et al. (2016) found that  
67 the Version 1.0 data generally agree with ground-based GPS data over land but are significantly  
68 lower than the microwave observations over the oceans. They found that using a narrower  
69 retrieval window (427.7 – 465 nm) in Version 2.1 could improve the data over the oceans  
70 without adversely affecting the results over land much. However, the Version 2.1 data were only  
71 generated for a few test months and not released to the public. An interim Version 3.0 OMI  
72 TCWV product was available at AVDC. Compared with Version 2.1, Version 3.0 uses the  
73 reference spectrum for water vapor from the latest HITRAN database (Gordon et al., 2016) and  
74 that for liquid water from Mason et al. (2016), as well as the newest cloud product (Veefkind et  
75 al., 2016). The Version 3.0 retrieval window (427.0 – 467.0 nm) is adjusted from that for  
76 Version 2 within 2 nm on each end based on fitting uncertainty for a randomly selected test orbit.

77 This paper focuses on Version 4.0 OMI TCWV which has replaced Version 3.0 on AVDC.  
78 We present the Version 4.0 retrieval algorithm which incorporates a more vigorous systematic  
79 optimization for the retrieval window and miscellaneous updates. We characterize the  
80 performance of the Version 4.0 dataset by comparing with well-established references, such as  
81 the GPS network data and the Special Sensor Microwave Imager / Sounder (SSMIS)  
82 observations. We also assess the performance of Version 4.0 against that of Version 3.0. To  
83 provide practical guide to users of the new data, we investigate the influence of cloud fraction  
84 and cloud top pressure on the comparisons. Based on the results, data filtering criteria are  
85 recommended. As an additional check on the Version 4.0 product, we show test applications of  
86 the data to a range of spatial and temporal scales, including El Niño / La Niña, a corn sweat  
87 event and an atmospheric river (AR) event. For the first time, a data assimilation experiment for  
88 the AR event demonstrates that the OMI TCWV data can provide useful constraint for weather  
89 prediction.

## 90 **2 Retrieval Algorithm**

91 OMI on board the Aura spacecraft is a UV/Visible imaging spectrometer (Levelt et al.,  
92 2006). It has been making daily global observations at a nominal  $13 \times 24$  km nadir resolution  
93 from a 1:30 PM equator crossing time polar orbit since October 2004. The UV-Visible channel  
94 of OMI covers 350-500 nm at a spectral resolution of about 0.5 nm.

95 TCWV is derived from the OMI visible spectrum using a commonly used two-step approach.  
96 First, the Slant Column Density (SCD, molecules/cm<sup>2</sup>) is retrieved from a spectral fitting  
97 algorithm. Then, the Vertical Column Density (VCD, molecules/cm<sup>2</sup>) is calculated from the ratio  
98 of SCD and Air Mass Factor (AMF) (Palmer et al., 2001). VCD can be converted to TCWV  
99 using  $10^{23}$  molecules/cm<sup>2</sup> = 29.89 mm. The details of the two-step procedure can be found in  
100 González Abad et al. (2015). The specifics of Version 4.0 are discussed below.

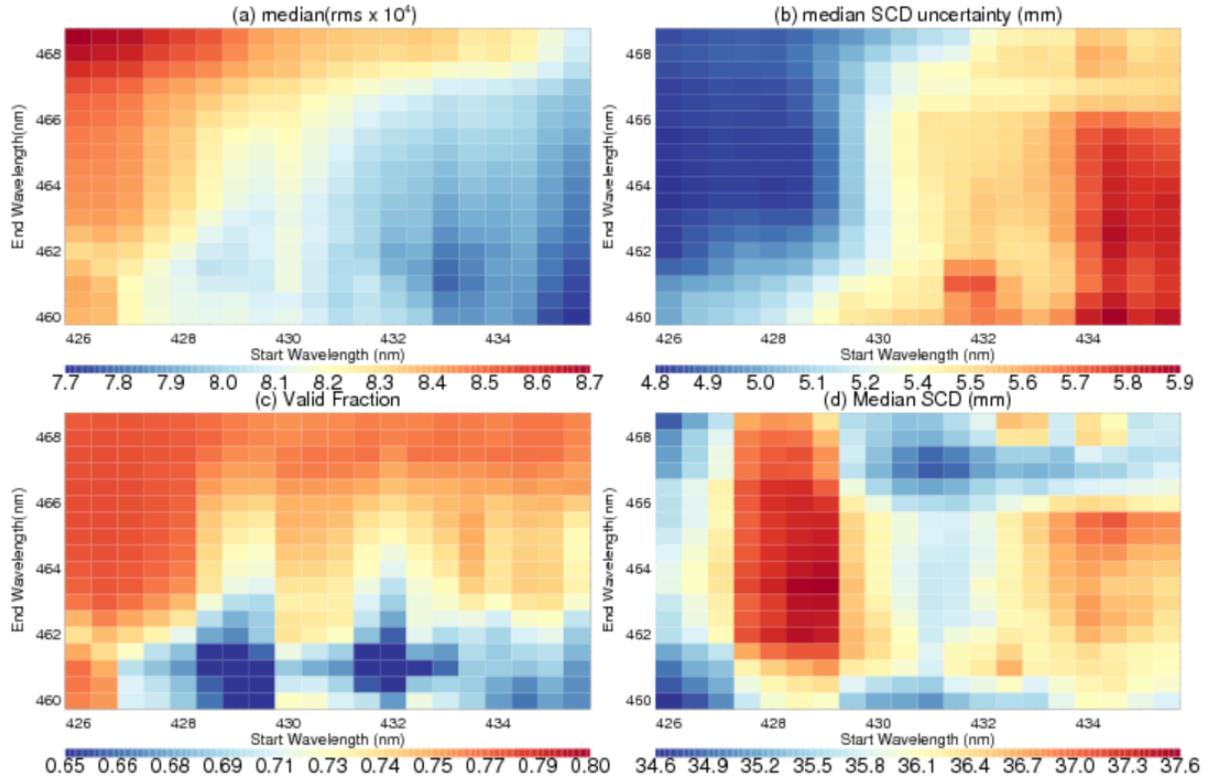

101 The Version 4.0 spectral fitting parameters are summarized in Table 1. In the nonlinear least  
102 square fitting, we consider wavelength shift, under-sampling, closure polynomials (3<sup>rd</sup> order  
103 multiplicative and additive), reference spectroscopic spectra of water vapor, interfering  
104 molecules (O<sub>3</sub>, NO<sub>2</sub>, O<sub>4</sub>, liquid water, C<sub>2</sub>H<sub>2</sub>O<sub>2</sub> and IO) and Raman scattering (the Ring effect,  
105 vibrational Raman scattering of air and the water Ring effect). In comparison with previous  
106 versions, Version 4.0 no longer fits common mode (i.e. the mean of the fitting residual, González  
107 Abad et al., 2015). It turns out that the common mode for land is different than that for ocean  
108 (Wang et al., 2014). Previous retrievals derive a common mode for each orbit swath using the  
109 pixels in the low latitudes which often includes both land and ocean scenes. Thus, the derived  
110 common mode depends on the proportion of land versus ocean pixels of the spacecraft orbit and  
111 is not universally suitable for all the pixels of the swath. Statistics for Orbit 10423 show that  
112 although the mean of SCD differs little between the retrievals with and without common mode in  
113 the fitting (0.1 mm), the standard deviation of SCD between them can be significant (1.7 mm).  
114 Most of the settings in Table 1 are shared between Version 3.0 and 4.0, except that Version 3.0  
115 uses HITRAN 2016 (Gordon et al., 2016) as the water vapor reference spectrum, includes  
116 common mode in the fitting, but does not consider vibrational Raman scattering of air (Lampel et  
117 al., 2015a). We revert to the HITRAN 2008 water vapor spectrum (Rothman et al., 2009) in  
118 Version 4.0 because validation results show that it leads to better agreements with the GPS and  
119 SSMIS TCWV data (Section 3). We did not apply the correction of Lampel et al. (2015b) to the

120 HITRAN 2008 water vapor spectrum. It is recently found that HITRAN 2016 is adversely  
 121 affected by an issue with line broadening for water vapor in the blue wavelength range and  
 122 improvements are being made for the next HITRAN release (the HITRAN group, personal  
 123 communication).

124 **Table 1.** Parameters used in Version 4.0 spectral fitting for OMI total column water vapor.

Wavelength shift	Solar reference spectrum	Dobber et al. (2008)
Target	H <sub>2</sub> O	288K, Rothman et al. (2009)
Interference molecules	O <sub>3</sub>	228K, Brion et al. (1993)
	NO <sub>2</sub>	220K, Vandaele et al. (1998)
	O <sub>4</sub>	293K, Thalman and Volkamer (2013)
	Liquid water	Mason et al. (2016)
	C <sub>2</sub> H <sub>2</sub> O <sub>2</sub>	296K, Volkamer et al. (2005)
	IO	298K, Spietz et al. (2005)
Raman scattering	Ring effect	Chance and Spurr (1997)
	Water Ring	Chance and Spurr (1997)
	Air Vibrational Raman	Lampel et al. (2015a)
Other	Additive polynomial	3 <sup>rd</sup> order
	Multiplicative polynomial	3 <sup>rd</sup> order
	Under-sampling	Chance et al. (2005)

125  
 126 To optimize the retrieval window, we randomly selected OMI Orbit number 10426 (on July  
 127 1, 2006) to examine the effect of varying the starting and ending wavelengths around the 7v  
 128 water vapor absorption band. The orbit swath contains 60×1644 ground pixels and covers parts  
 129 of Australia, the Pacific, China and other areas. We systematically adjust the starting wavelength  
 130 within 426.0-435.0 nm and the ending wavelength within 460.0-468.5 nm, both at 0.5 nm steps.

131

132 **Figure 1.** Sensitivity of the retrieval to the start and end wavelengths (nm) of the retrieval  
 133 window for OMI Orbit number 10426. (a) Median of fitting RMS $\times 10^4$ ; (b) median of water  
 134 vapor SCD fitting uncertainty in mm; (c) valid fraction for retrievals; (d) median SCD in mm.

135 In previous versions, the fitting window is selected based on the fitting uncertainty (Wang et  
 136 al., 2014, 2016). For Version 4.0, we consider the following four factors. (1) Figure 1a shows  
 137 that the median of the fitting Root Mean Squared error (RMS) is smaller toward the lower right  
 138 corner of the domain (i.e., longer start wavelength and shorter end wavelength); (2) Figure 1b  
 139 shows that the medium fitting uncertainty of water vapor SCD decreases toward the upper left  
 140 corner; (3) Figure 1c shows that the fraction of valid retrievals for the orbit generally increases  
 141 toward the upper part of the domain. Valid retrievals here refer to those that pass the main data  
 142 quality check (MDQFL = 0) and have positive SCDs. The main data quality check ensures that  
 143 the fitting has converged, the SCD is  $< 5 \times 10^{23}$  molecules/cm<sup>2</sup> (149.45 mm) and within  $2\sigma$  of the  
 144 fitting uncertainty. The SCD threshold here is meant to filter out large outliers. For reference, the  
 145 largest TCWV of the GPS and SSMIS datasets used in Section 3 is about 75 mm. At low  
 146 latitudes where TCWV is large, more than 90% of the OMI AMFs are between 0.5 and 2.0; (4)  
 147 The length of the retrieval window increases with the difference between the end and start

148 wavelengths. The general patterns exhibited by Orbit number 10426 in Figure 1 also hold for  
149 Orbit number 10423 which cuts across the Pacific near the dateline.

150 Ideally, we would like to have small fitting RMS to reduce the residual's amplitude and  
151 structure, a small fitting uncertainty to reduce error, a large fraction of valid data to increase data  
152 volume and a long retrieval window to include more information into the fitting. However, these  
153 criteria cannot be met simultaneously. As a compromise, we select the wavelength interval  
154 between 432.0 nm and 466.5 nm as the retrieval window for Version 4.0. For Orbit number  
155 10426, this leads to a median fitting RMS of  $8.1 \times 10^{-4}$ , a median SCD uncertainty of 5.4 mm, a  
156 valid fraction of 0.75 and a window length of 34.5 nm (Figure 1). Figure 1d shows that the  
157 median SCD for Orbit number 10426 varies between 34.6 mm and 37.6 mm. This 3 mm  
158 difference corresponds to an 8% variation and exhibits a complex pattern within the domain. The  
159 Version 4.0 retrieval window leads to a median SCD of 35.5 mm for Orbit number 10426 which  
160 is near the beginning of the middle third of the SCD range. The ratio between the median SCD  
161 uncertainty and the median SCD (i.e., the relative SCD uncertainty) is about 0.15. Note that this  
162 value is for the whole orbit which includes a wide range of SCDs. As shown in Supplementary  
163 Figure 1, the relative SCD uncertainty is  $>1.2$  for  $SCD = 0 - 10$  mm, drops to about 0.4 for  $SCD$   
164  $= 10 - 20$  mm, and to about 0.1 for  $SCD > 40$  mm.

165 The AMF is calculated by convolving scattering weights with the shape of water vapor  
166 vertical profile (González Abad et al., 2015). The scattering weight is interpolated from the same  
167 look-up table as that used in Wang et al. (2016). The scene specific information used in the AMF  
168 calculation is listed in Table 2. By propagating typical errors for surface albedo (15%), cloud  
169 fraction (10%) and cloud top pressure (15%), we find that the AMF error due to scattering  
170 weight for a typical orbit (number 10426) is mostly  $< 3\%$ , though for cloudy pixels, the error can  
171 be 15% or more. Version 4.0 uses the  $0.5^\circ \times 0.667^\circ$  monthly mean MERRA-2 water vapor profile  
172 (Gelaro et al., 2017) for the month and year corresponding to the retrieval, while previous  
173 versions used the monthly mean of 2007 for all years. To evaluate the error associated with gas  
174 profiles, we compare the TCWV calculated using the daily MERRA-2 profile against that  
175 calculated using the monthly MERRA-2 profile for July 2006 (for TCWV within the 0 – 75 mm  
176 range). Results show that  $(TCWV(\text{daily}) - TCWV(\text{monthly}))$  has a mean (median) of 0.3 mm (0  
177 mm) with a standard deviation of 5.0 mm. When comparing the TCWV calculated using the  
178 daily MERRA-2 profile against that calculated using the daily ERA-Interim profile for July

179 2006, we find that (TCWV(MERRA-2) – TCWV(ERA-Interim)) has a mean (median) of -0.1  
 180 mm (0 mm) with a standard deviation of 2.8 mm. Thus, gas profiles can introduce substantial  
 181 scatter to the retrieved TCWV. AMF is highly sensitive to clouds (Wang et al., 2014; Vasilkov et  
 182 al., 2017). Version 4.0 uses the cloud information from Veefkind et al. (2016). The primary  
 183 difference with the Acarreta et al. (2004) cloud product used in Version 1.0 and 2.1 is in the  
 184 cloud top pressure for cloud fraction  $f < 0.3$ . In addition to the factors in Table 2, aerosol and  
 185 surface bi-directional reflectance distribution function (BRDF) influence the AMF (Lorente et  
 186 al., 2017; Vasilkov et al., 2017), but have not been considered in the retrieval yet.

187 **Table 2.** Parameters used in AMF calculation

Solar Zenith Angle	OMI L1B data
View Zenith Angle	
Relative Azimuth Angle	
Surface Albedo	OMLER (Lambert equivalent reflectance) Kleipool, et al. (2008)
Cloud fraction	OMCLDO2 (derived from O <sub>2</sub> -O <sub>2</sub> ) Veefkind et al. (2016)
Cloud top pressure	
Surface pressure	MERRA-2 monthly data (0.5°×0.667°), Gelaro et al. (2017)
Water vapor profile	

188

### 189 3 Validation

190 To validate the Version 4.0 OMI TCWV data, we compare them against two commonly used  
 191 reference datasets – a GPS network dataset for land and a microwave dataset for the oceans.

#### 192 3.1 OMI and GPS over land

193 To assess the Version 4.0 OMI TCWV over land, we compare against the GPS network data  
 194 downloaded from NCAR (rda.ucar.edu/datasets/ds721.1). The GPS data are composed of 2-  
 195 hourly TCWV at International GNSS Service (IGS), SuomiNet and GEONET stations, and have  
 196 an estimated error of  $< 1.5$  mm (Wang et al., 2007; Ning et al., 2016). The subset of IGS-  
 197 SuomiNet data for the whole year of 2006 is used in this paper. The geographical distribution of  
 198 the stations can be found in Wang et al. (2016). Most of the stations are concentrated in North  
 199 America and Europe, fewer are scattered on other continents.

200 OMI TCWV data are filtered using the following criteria. The stripes in Level 2 swaths due  
 201 to systematic instrument error are removed using the SCD scaling procedure described in Wang

202 et al. (2016). The pixels affected by OMI's row anomaly are filtered out  
203 ([projects.knmi.nl/omi/research/product/rowanomaly-background.php](http://projects.knmi.nl/omi/research/product/rowanomaly-background.php)), as well as negative or  
204 extremely large (i.e., TCWV > 75 mm) values. For the clear-sky comparison in Figure 3, we  
205 require cloud fraction < 5% and cloud top pressure > 750 mb, in addition to MDQFL = 0 and  
206 fitting RMS < 0.001. The cloud fraction and cloud top pressure are from the OMCLDO2 cloud  
207 product (Veefkind et al., 2016) and are included in the Level 2 OMI product for ease of data  
208 filtering. On a typical day (July 1, 2006), among the OMI data that pass the MDQFL and TCWV  
209 range test, cloud fraction < 0.05 accounts for 35% of the data, cloud top pressure > 750 mb  
210 accounts for 53% of the data and RMS < 0.001 accounts for 72% of the data.

211 To co-locate GPS and OMI data, we select the GPS data observed between 1200 LT and  
212 1500LT. This 3-hour local time range covers the OMI overpass time. We average the qualified  
213 OMI data within  $0.25^\circ$  longitude  $\times$   $0.25^\circ$  latitude of the GPS stations for each day. To minimize  
214 the influence of local topography (e.g., mountain peaks, river valleys), if a station's elevation is  
215 more than 250 m different than the mean elevation within the corresponding  $0.25^\circ \times 0.25^\circ$  grid  
216 square, then it is excluded from the analysis. The  $0.25^\circ \times 0.25^\circ$  topography was downloaded from  
217 [www.temis.nl/data/topo/dem2grid.html](http://www.temis.nl/data/topo/dem2grid.html). The comparison between OMI and GPS is made for  
218 TCWV within the range of 0 – 75 mm as the largest TCWV for the GPS data is about 75 mm.  
219 The co-locating procedure leads to about 11,000 co-located data points for the entire year of  
220 2006.

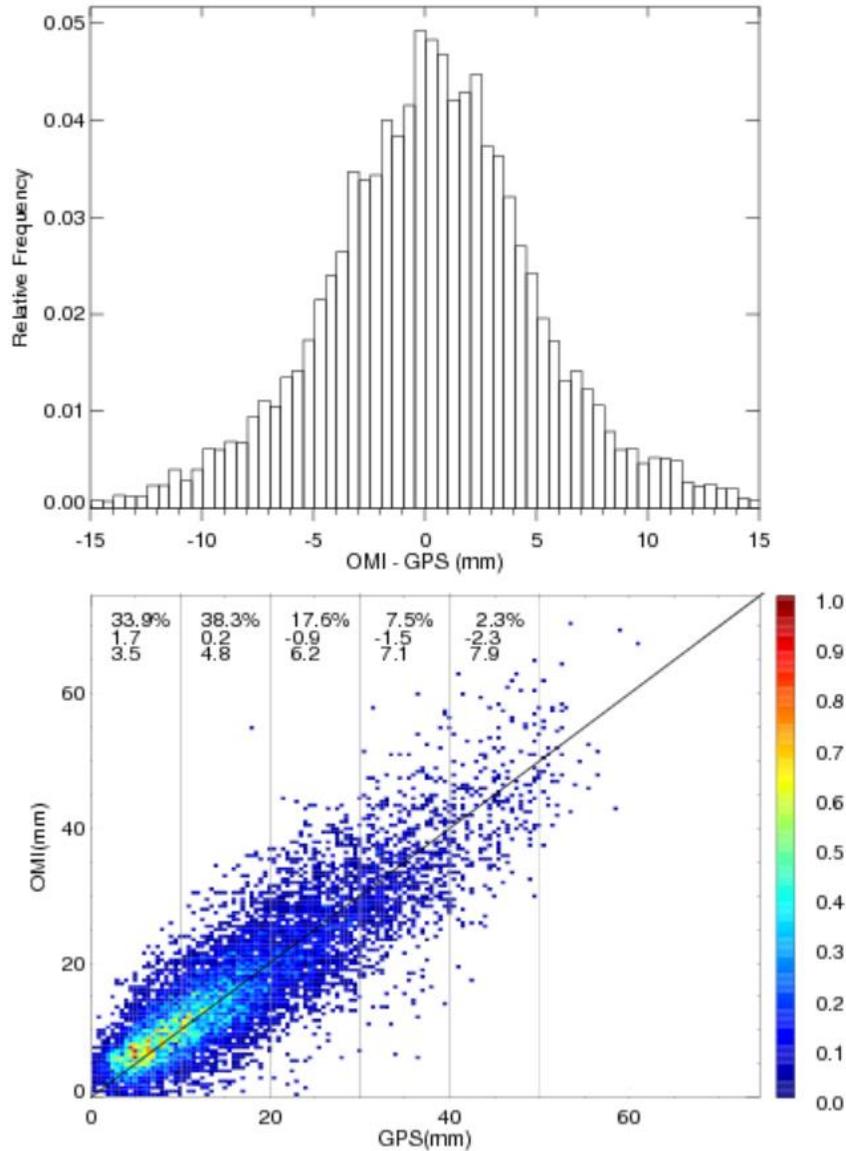

221 Figure 2 shows the comparison between the resulting co-located GPS and Version 4 OMI  
222 TCWV. The top panel shows the histogram of OMI-GPS (in 0.5 mm bins). The bin from -0.5 to  
223 0.0 mm corresponds to the peak of the distribution. The overall mean (median) of OMI-GPS is  
224 0.32 mm (0.35 mm), with a standard deviation of 5.2 mm. The mean (median) absolute error is  
225 3.9 mm (3.0 mm).

226 The bottom panel of Figure 2 shows the joint distribution of the co-located GPS and Version  
227 4.0 OMI data. The count for each 0.5 mm bin is normalized by the maximum of all bins. About  
228 34% of the data have TCWV < 10 mm, 72% have TCWV < 20 mm and 90% have TCWV < 30  
229 mm. There is a general linear correlation between GPS and OMI data, with a correlation  
230 coefficient of  $r = 0.87$  ( $R^2 = 0.76$ ). The linear regression line ( $\text{OMI} = 2.22 + 0.88 * \text{GPS}$ , where  
231 OMI and GPS TCWV are in mm) has a significant positive intercept and a slope that is less than

232 one. This indicates a positive bias of OMI against GPS for small TCWV and a negative bias for  
233 large TCWV. Indeed, as indicated at the top of the panel, the mean of OMI-GPS for each 10 mm  
234 GPS TCWV bin decreases from 1.7 mm for TCWV = 0 – 10 mm to -2.3 mm for TCWV = 40 –  
235 50 mm, though the fraction of data for TCWV > 40 mm is < 3%. The corresponding standard  
236 deviation ( $\sigma$ ) increases from 3.5 mm to 7.9 mm. The minimum bias of 0.2 mm occurs for TCWV  
237 in the 10 – 20 mm bin. The large positive bias of the 0 – 10 mm bin (as compared with the  
238 TCWV of the bin) has significant adverse effect on the regression line. For TCWV > 10 mm, the  
239 regression line ( $OMI = 1.51 + 0.91 \times GPS$ ) is better.

240 In comparison, although Version 3.0 OMI is similarly correlated with GPS (correlation  
241 coefficient  $r = 0.86$ ), it has a much larger positive bias of 2.8 mm (with a standard deviation of  
242 5.5 mm). The large bias is attributed to the much larger SCD of Version 3.0 (Supplementary  
243 Figure 2b), as the AMFs of both versions roughly follow the 1:1 line (Supplementary Figure 2a).  
244 Sensitivity tests show that the larger Version 3.0 SCD is primary due to the water vapor  
245 reference spectrum. If the water vapor reference spectrum in Version 4.0 is replaced with that of  
246 Version 3.0 (Test 1), then the median SCD increases by about 4.5 mm for Orbit 10423  
247 (Supplementary Figure 2c). Modifying the retrieval window for Version 3.0 cannot sufficiently  
248 reduce the retrieved SCD, therefore cannot make significantly better agreement with the  
249 reference TCWV data. As Version 4.0 shows better performance, this paper focuses on  
250 characterizing Version 4.0 to provide useful information to potential users. In subsequent  
251 discussions, OMI data refer to Version 4.0 unless specified otherwise.

252

253

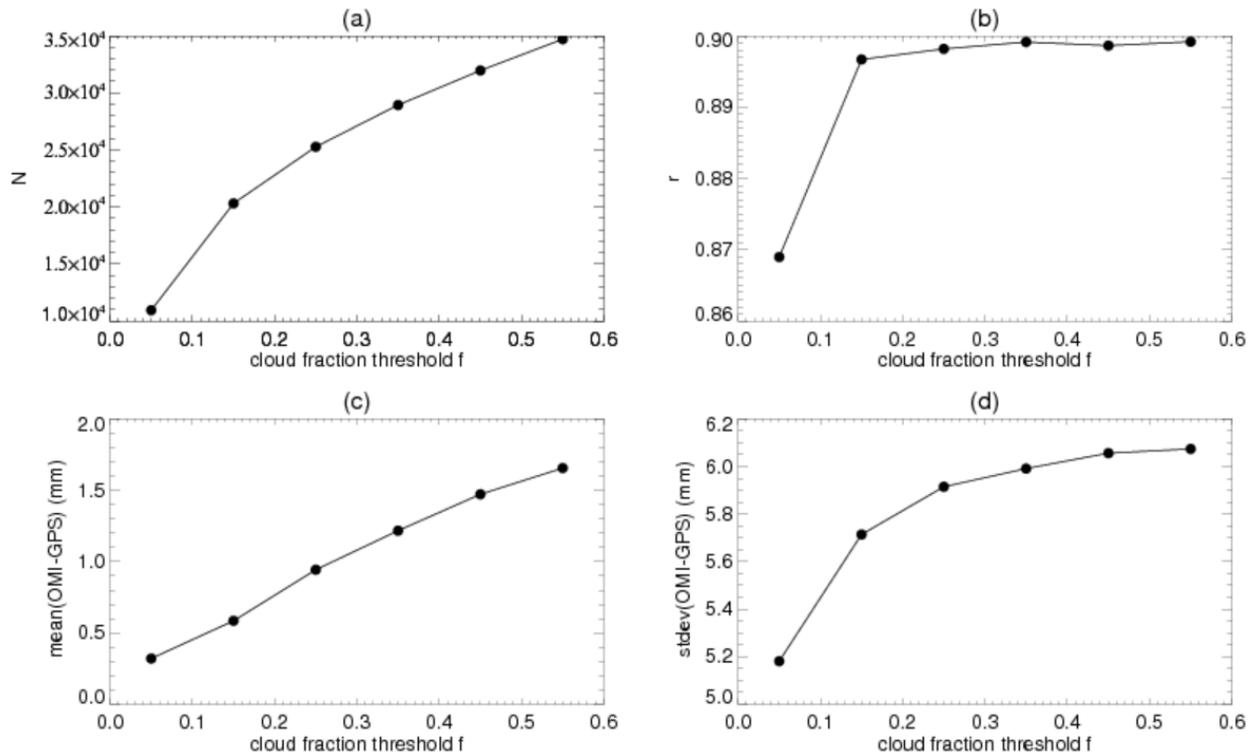

254 **Figure 2.** Comparison between co-located GPS and OMI TCWV (mm) for all days in 2006. The  
 255 data filtering criteria include cloud fraction < 5%, cloud top pressure > 750 mb, and others  
 256 discussed in the text. (Top) Relative frequency of occurrence for OMI-GPS (mm). (Bottom)  
 257 Normalized joint distribution of GPS versus OMI TCWV (mm). The three lines of text from top  
 258 to bottom indicate the percentage of data points (1st), the mean of OMI-GPS in mm (2nd), and  
 259 the standard deviation of OMI-GPS in mm (3rd) for each 10 mm GPS TCWV, respectively. The  
 260 1:1 is plotted for reference.

261

262 OMI TCWV retrieval is highly sensitive to clouds (Wang et al., 2014). In Figure 3, we  
263 examine the effect of OMI cloud fraction threshold ( $f$ ) on the comparison while keeping other  
264 data filtering criteria the same as those for Figure 2 (i.e., cloud fraction  $< f$ , cloud top pressure  $<$   
265 750 mb, MDQFL = 0, fitting RMS  $< 0.001$  and  $0 < \text{TCWV} < 75$  mm). From  $f = 0.05$  to  $f = 0.55$ ,  
266 the number of co-located data pairs ( $N$ ) more than triples, the mean of OMI-GPS increases from  
267 0.32 mm to 1.66 mm, the standard deviation of OMI-GPS increases from 5.2 mm to 6.1 mm. The  
268 linear correlation coefficient ( $r$ ) increases from  $r = 0.87$  at  $f = 0.05$  to  $r \sim 0.90$  at  $f = 0.15$ , then  
269 levels off for larger cloud fraction thresholds. It should be noted that the error in cloud top  
270 pressure decreases with cloud fraction in the OMCLDO2 product (Veefkind et al., 2016). As a  
271 result,  $f = 0.05$  corresponds to the largest uncertainty in cloud top pressure, and the error will  
272 propagate into OMI TCWV through AMF, leading to smaller correlation coefficient than those  
273 for larger  $f$  values.

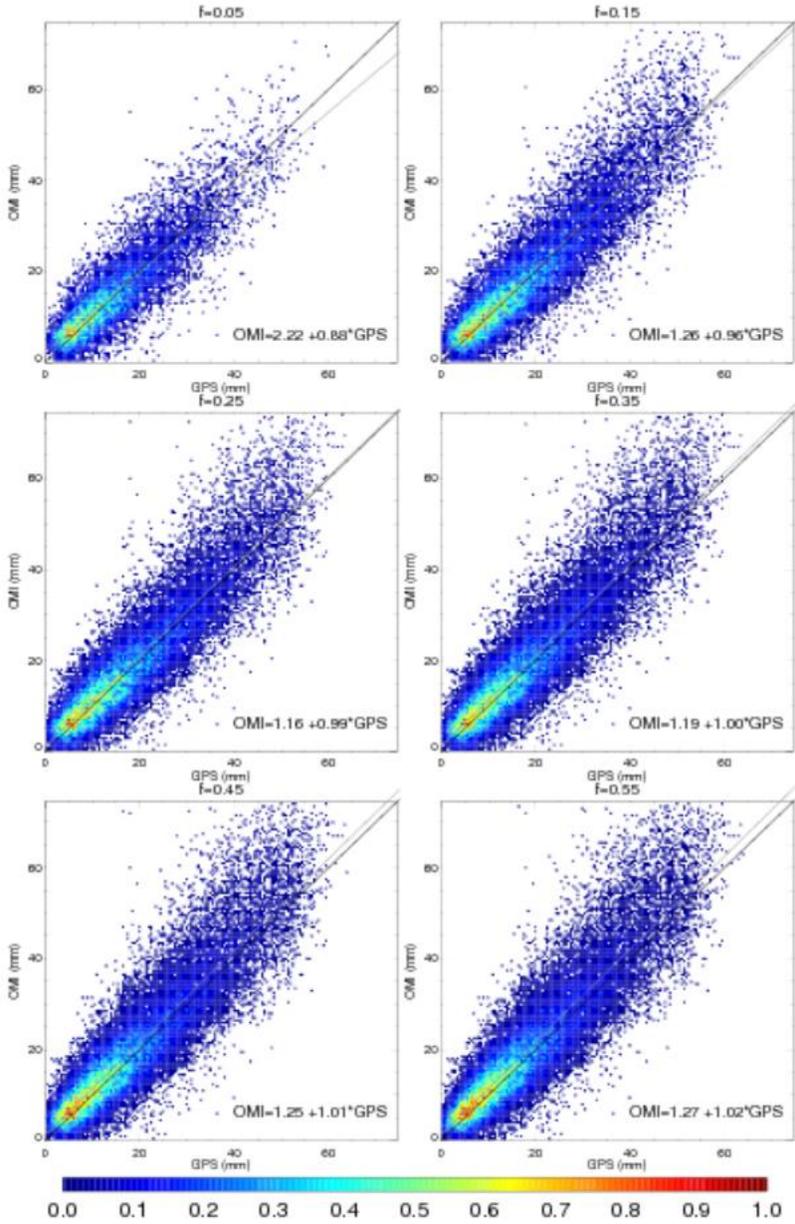

274 In addition, as shown by the GPS versus OMI joint distributions for different cloud fraction  
275 thresholds in Figure 4, the  $f \geq 0.15$  cases have larger effective dynamical ranges which tend to  
276 favor better correlations. For example, there is a larger fraction of data pairs with TCWV  $> 30$   
277 mm for  $f = 0.15$  than for  $f = 0.05$ . The regression line for  $f = 0.15$  ( $\text{OMI} = 1.26 + 0.96 * \text{GPS}$ )  
278 shows an apparent improvement over that for  $f = 0.05$  ( $\text{OMI} = 2.22 + 0.88 * \text{GPS}$ ). The best  
279 regression line is arguably that for  $f = 0.25$  ( $\text{OMI} = 1.16 + 0.99 * \text{GPS}$ ) or  $f = 0.35$  ( $\text{OMI} = 1.19 +$   
280  $1.00 * \text{GPS}$ ), though the mean bias and scatter are larger than those for  $f < 0.25$  (Figure 4).

281 In brief,  $f = 0.05$  leads to the lowest overall bias and scatter of the co-located data;  $f = 0.15$   
282 doubles the number of co-located data pairs and leads to the largest improvement in the  
283 correlation coefficient;  $f = 0.25$  (or 0.35) leads to the best linear regression line; the bias and  
284 standard deviation increase with cloud fraction threshold. Hence, cloud fraction thresholds in the  
285 range of  $f = 0.05 - 0.25$  seems reasonable for filtering OMI TCWV, depending on applications.

286

287 **Figure 3.** Dependence of various parameters on the cloud fraction threshold ( $f$ ) used for filtering  
 288 OMI data. Other filtering criteria remain the same as those for Figure 2. The parameters are (a)  
 289 number of co-located OMI and GPS data pairs; (b) linear correlation coefficient between OMI  
 290 and GPS TCWV; (c) mean of OMI-GPS in mm; (d) standard deviation of OMI-GPS in mm.  
 291 Results are derived from the co-located Version 4.0 OMI and GPS data for the whole year of  
 292 2006.

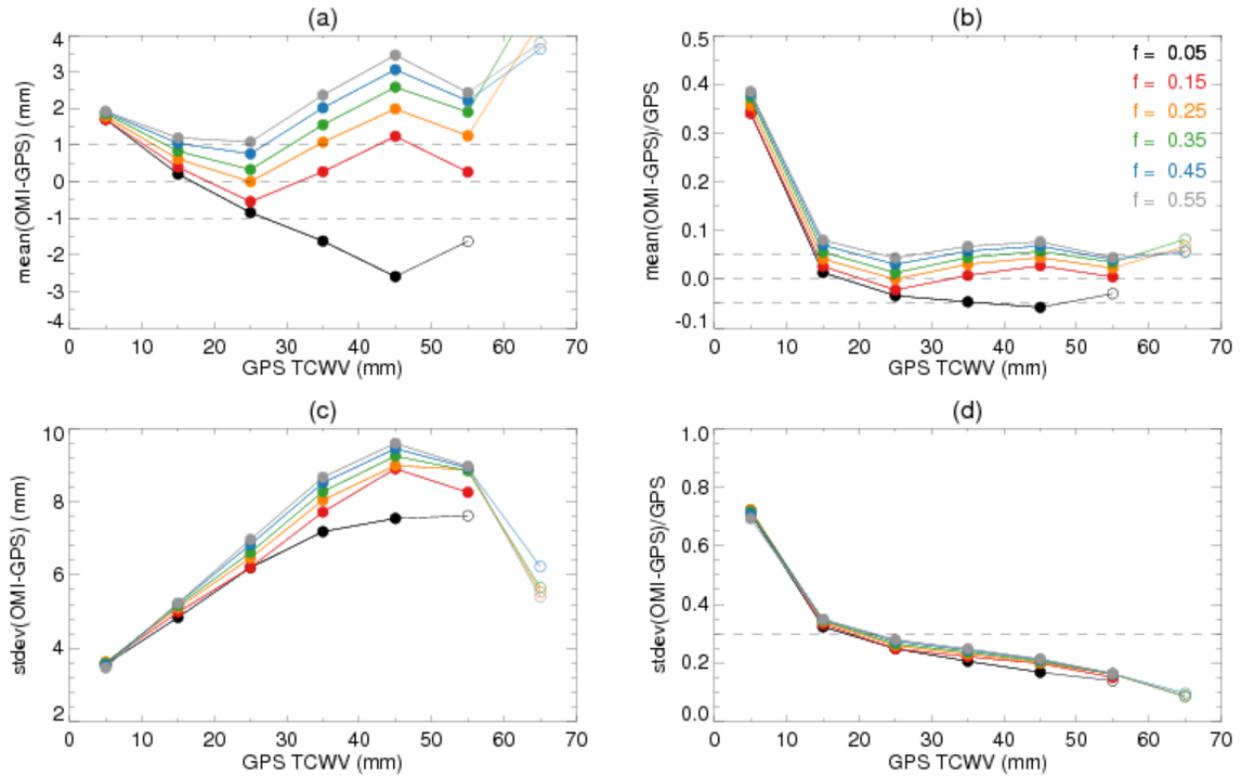

293

294 Figure 4. Normalized joint distributions of GPS versus Version 4.0 OMI TCWV for different  
 295 cloud fraction thresholds. Results are derived from the co-located data pairs for 2006. The OMI  
 296 data filtering criteria are the same as those for Figure 3. In each panel, the 1:1 line is plotted in  
 297 black, the linear regression line is plotted in gray and indicated by the formula in the lower right  
 298 corner.

299 To further characterize the effect of cloud fraction threshold on the comparison between GPS  
 300 and OMI, in Figure 5, we examine the mean and standard deviation ( $\sigma$ ) of OMI-GPS for each 10  
 301 mm GPS TCWV bin. The results are derived from the same sets of co-located GPS and OMI

302 data as those used in Figure 3 and Figure 4. The filled symbols are for the cases where the  
 303 number of GPS and OMI data pairs within the corresponding TCWV bin is  $> 1\%$  of the total  
 304 number of data pairs, and the open symbols are for  $< 1\%$ . As the filled symbols represent better  
 305 statistics, we will focus on them below.

306

307 **Figure 5.** Parameters for each 10 mm TCWV bin. Curves with different colors are for different  
 308 cloud fraction thresholds  $f$  as indicated in Panel (b). The OMI filtering criteria remain the same  
 309 as those for Figure 3 and 4. Symbols are filled if the fraction of data pairs within the TCWV  
 310 interval is  $> 1\%$  of all the available data pairs and are open otherwise. The parameters are (a)  
 311 mean of OMI-GPS in mm, (b) relative bias defined as  $\text{mean}(\text{OMI-GPS})/\text{GPS}$ , (c) standard  
 312 deviation ( $\sigma$ ) of OMI-GPS in mm, and (d) relative scatter defined as  $\sigma/\text{GPS}$ . Results are for all  
 313 days in 2006. Dashed lines are meant to facilitate visualization.

314

315 Figure 5(a) shows that the means of OMI-GPS vary between  $\pm 4$  mm following “V”-shaped  
 316 curves whose minima occur in the  $\text{TCWV} = 20 - 30$  mm bin except for  $f = 0.05$ . The curves shift  
 317 upward with increasing cloud fraction thresholds, suggesting that OMI cloudy-sky TCWV is  
 318 generally larger than OMI clear-sky TCWV. Other things being equal, cloud formation indicates

319 water vapor saturation and therefore a larger amount of TCWV than that under clear-sky  
320 condition. The smallest absolute bias for  $10 < \text{TCWV} < 20$  mm occurs at  $f = 0.05$ , that for  $20 <$   
321  $\text{TCWV} < 30$  mm occurs at  $f = 0.25$ , and that for  $30 < \text{TCWV} < 40$  mm occurs at  $f = 0.15$ . The  $f =$   
322  $0.15$  and  $f = 0.25$  curves show the best overall performance according to Figure 5(a) as they are  
323 within 1 mm of zero for  $10 < \text{TCWV} < 40$  mm, while other curves come within 1 mm of zero in  
324 narrower TCWV ranges. Figure 5(b) shows the relative bias which is defined as the mean of  
325  $(\text{OMI-GPS})/\text{GPS}$ . The relative biases decrease sharply from  $\sim 40\%$  to  $\sim 5\%$  as GPS TCWV  
326 increases from the  $\text{TCWV} = 0 - 10$  mm bin to the  $\text{TCWV} = 10 - 20$  mm bin, and generally stay  
327 less than  $\sim 5 - 10\%$  for larger TCWV values. Figure 5(c) shows that  $\sigma$  increases from  $\sim 3.5$  mm  
328 for  $\text{TCWV} = 0 - 10$  mm to  $\sim 9.5$  mm for  $\text{TCWV} = 40 - 50$  mm (the percentage of data with  
329  $\text{TCWV} > 50$  mm is very small). In most cases, larger cloud fraction thresholds correspond to  
330 larger  $\sigma$  values. This is consistent with the larger dynamical range (due to a larger fraction of  
331 data with high TCWV) for larger cloud fraction threshold (Figure 4). In fact, the relative scatter,  
332 defined as the mean of  $\sigma/\text{TCWV}$ , shows little difference among the  $f$  values (Figure 5d). The  
333 relative scatter decreases with TCWV, with the sharpest decrease from  $\sim 0.7$  to  $\sim 0.3$  between  
334  $\text{TCWV} = 0 - 10$  mm and  $\text{TCWV} = 10 - 20$  mm (Figure 5d). The relative scatter continues to  
335 decrease for larger TCWV and the overall scatter is about 20%.

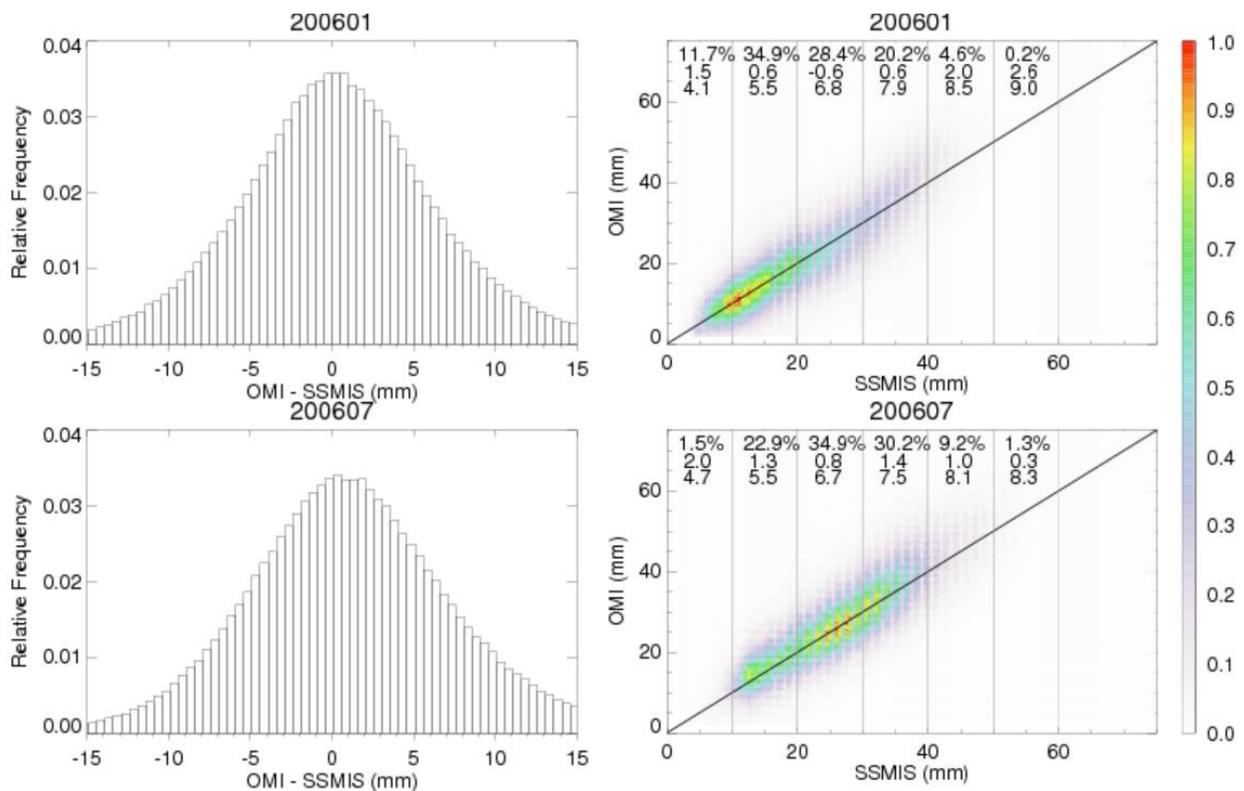

336 In short, Version 4.0 OMI agrees with GPS within 1 mm for  $10 < \text{TCWV} < 40$  mm when  $f =$   
337  $0.15$  and  $f = 0.25$  are used; when  $f = 0.05$  is used, the bias and scatter are the smallest for  
338  $10 < \text{TCWV} < 20$  mm; but, for  $\text{TCWV} < 10$  mm, OMI TCWV is too high and has large relative  
339 scatter. The latter is expected from the low signal-to-noise ratio when  $\text{TCWV} < 10$  mm in the  
340 OMI retrieval.

### 341 **3.2 OMI and SSMIS over ocean**

342 To evaluate Version 4.0 OMI TCWV over the oceans, we compare against the microwave  
343 TCWV data from SSMIS on board the Defense Meteorological Satellite Program (DMSP)'s F16  
344 satellite. The SSMIS data are derived by Remote Sensing Systems (RSS) using their Version 7  
345 algorithm ([www.remss.com](http://www.remss.com)) and have a retrieval accuracy of better than 1 mm (Wentz, 1997;  
346 Mears et al., 2015). For clear-sky comparison, we use the daily  $0.25^\circ \times 0.25^\circ$  SSMIS data for  
347 January and July 2006 and filter out the pixels affected by rain and cloud liquid water. Diedrich  
348 et al. (2016) found that the diurnal cycle in TCWV is generally within 1% to 5% of the daily

349 mean, with a minimum between 0600 LT and 1000 LT and a maximum between 1600 LT and  
 350 2000 LT. To reduce the influence of diurnal cycle, we average the SSMIS data for the ascending  
 351 and descending orbits of F16 (~2000 LT and 0800 LT in 2006).

352 We generate daily  $0.25^\circ \times 0.25^\circ$  Level 3 OMI TCWV from the de-striped Level 2 OMI  
 353 swaths, with the requirement that MDQFL = 0, fitting RMS < 0.001,  $0 < \text{TCWV} < 75$  mm, cloud  
 354 fraction < 0.05, and cloud top pressure > 750 mb. There are typically 15 Level 2 swaths per day.  
 355 The gridding program uses a tessellation method that weighs the contribution of a Level 2 data  
 356 point by its area within the Level 3 grid square and its spectrum fitting uncertainty (Wang et al.,  
 357 2014, 2016). The filtered daily Level 3 SSMIS and OMI data are compared for each month. We  
 358 find 548,223 and 847,678 co-located data pairs for January and July 2006, respectively.

359

360 **Figure 6.** Comparisons between Version 4.0 OMI and SSMIS over the oceans for (top) January  
 361 2006 and (bottom) July 2006. Panels in the left column show the relative occurrence frequency  
 362 of OMI-SSMIS (mm). Panels in the right column show the normalized joint distribution of  
 363 SSMIS versus OMI TCWV (mm).

364

365 The left column of Figure 6 shows the distribution of OMI-SSMIS for January and July  
366 2006. For July, the mean of OMI-SSMIS is 1.1 mm with a standard deviation of 6.8 mm, the  
367 mean absolute error  $|\text{OMI-SSMIS}|$  is 5.2 mm; for January, the mean error, standard deviation and  
368 mean absolute error are 0.4 mm, 6.5 mm and 5.0 mm, respectively. This suggests a slightly better  
369 agreement for January than for July. In comparison with the (OMI-GPS) over land (Section 3.1),  
370 OMI-SSMIS over the oceans has somewhat larger bias and standard deviation. However, as  
371 TCWV over the oceans are generally larger than that over land (compare Figure 6 with Figure  
372 2), the relative bias and scatter are actually similar.

373 The right column of Figure 6 shows the normalized joint distribution of SSMIS versus OMI  
374 for January and July 2006. The correlation coefficients are  $r = 0.84$  and  $0.82$  for January and  
375 July, respectively. For January, OMI-SSMIS remains within 0.6 mm of zero for TCWV in the 10  
376 – 40 mm range, but is 1.5 mm for TCWV in the 0 – 10 mm range (only a small fraction of data  
377 pairs have  $\text{TCWV} > 40$  mm); for July, OMI-GPS is 0.8 mm for the  $\text{TCWV} = 20 - 30$  mm bin,  
378 and varies between 0.8 and 1.4 mm for TCWV in the 10 – 50 mm range (only a small fraction of  
379 data pairs have  $\text{TCWV} < 10$  mm or  $> 50$  mm). For TCWV bins that have  $> 5\%$  of the data pairs,  
380 the standard deviation of OMI-SSMIS vary between 4.1 and 8.1 mm. Overall, Version 4.0 OMI  
381 data compare reasonably well with SSMIS data for TCWV in the 10 – 40 mm range, with the  
382 smallest bias occurring in the  $\text{TCWV} = 20 - 30$  mm bin.

383 The agreement between Version 4.0 OMI with SSMIS is better than that between Version 3.0  
384 OMI and SSMIS. For July 2006, using the same data filtering criteria as before, we find that  
385 Version 3.0 OMI – SSMIS has a mean of 3.2 mm with a standard deviation of 7.8 mm. The bias  
386 is much larger than that for Version 4.0 OMI – SSMIS. Again, this is because of the much larger  
387 SCD of Version 3.0 OMI TCWV due to the water vapor reference spectrum (Supplementary  
388 Figure 1).

389 Table 3 shows the effect of cloud fraction threshold ( $f$ ) on the comparison between SSMIS  
390 and Version 4.0 OMI TCWV. The comparisons are performed using daily filtered Level 3 data  
391 for July 2006. For SSMIS, we only filter out pixels affected by rain. To investigate the influence  
392 of clouds, cloud liquid water is not used to filter the SSMIS data here. This is less restrictive than  
393 the criteria used for Figure 6 as the SSMIS pixels with cloud liquid water are filtered out in  
394 Figure 6 for the “clear-sky” comparison there. For OMI, we require  $\text{MDQFL} = 0$ ,  $\text{RMS} < 0.001$ ,

395  $0 < \text{TCWV} < 75$  mm, cloud top pressure  $> 750$  mb and cloud fraction  $< f$ . Results show that OMI  
 396 is higher than SSMIS by 0.02 – 3.07 mm for  $f = 0.05 - 0.45$ . The difference between the  $f = 0.05$   
 397 case of Table 3 and the  $f = 0.05$  case of Figure 6 is due to the relaxed SSMIS filtering criteria.  
 398 The closest agreement in terms of the mean and standard deviation of OMI-SSMIS occurs when  
 399  $f = 0.05$ . The number of SSMIS and OMI data pairs more than doubles between  $f = 0.05$  and  $f =$   
 400 0.15. The linear correlation coefficient varies between 0.82 and 0.85 within the range of  $f$  values  
 401 considered. The best linear regression line ( $\text{OMI} = 0.70 + 1.02 * \text{SSMIS}$ ) occurs when  $f = 0.15$ .  
 402 Therefore, for OMI over the oceans, we recommend using cloud fraction threshold  $f = 0.05 -$   
 403 0.15, in combination with the other usual data filtering criteria, though users are advised to make  
 404 their own decisions based on their tolerance and applications.

405 **Table 3.** Effect of cloud fraction threshold on the comparison between SSMIS and Version 4.0  
 406 OMI TCWV for July 2006.  $f$ : OMI cloud fraction threshold;  $N$ : number of qualifying data pairs;  
 407  $P$ : Percentage of qualifying data pairs with respect to the total number of qualifying SSMIS data  
 408 points; Mean: mean of OMI-SSMIS in mm;  $\sigma$ : standard deviation of OMI-SSMIS in mm; MAE:  
 409 Mean absolute error  $|\text{OMI}-\text{SSMIS}|$  in mm;  $r$ : correlation coefficient between SSMIS and OMI;  
 410  $R^2$ : coefficient of determination for linear regression  $\text{OMI} = b + k * \text{SSMIS}$ , where OMI and  
 411 SSMIS are in mm;  $b$ : Intercept of linear regression;  $k$ : slope of linear regression.

$f$	$N$	$P$ (%)	Mean	$\sigma$	MAE	$r$	$R^2$	$b$	$k$
0.05	1,048,879	7.4	0.02	7.11	5.39	0.82	0.67	1.43	0.95
0.15	2,837,032	20.0	1.38	7.82	5.84	0.84	0.71	0.70	1.02
0.25	3,932,468	27.8	2.20	8.09	6.09	0.84	0.71	1.11	1.04
0.35	4,819,185	34.0	2.73	8.22	6.24	0.85	0.72	1.45	1.05
0.45	5,537,003	39.1	3.07	8.26	6.32	0.85	0.72	1.62	1.06

412  
 413 Lowering the value for cloud top pressure threshold also leads to larger bias and scatter. For  
 414 example, when cloud fraction threshold  $f = 0.05$  and cloud top pressure  $> 500$  mb are used, the  
 415 mean and standard deviation of OMI-SSMIS become 0.80 mm and 7.9 mm, both are larger than  
 416 those for  $f = 0.05$  in Table 3, though the linear regression line improves to  $\text{OMI} = 0.63 + 1.01 * \text{SSMIS}$   
 417 due to an increase in the dynamical range of TCWV. It should be noted that the OMCLDO2  
 418 cloud product shows good agreement with ground-based observations for clouds at altitudes  
 419 lower than 2.5 km where single cloud layers dominate, but shows significant bias and large

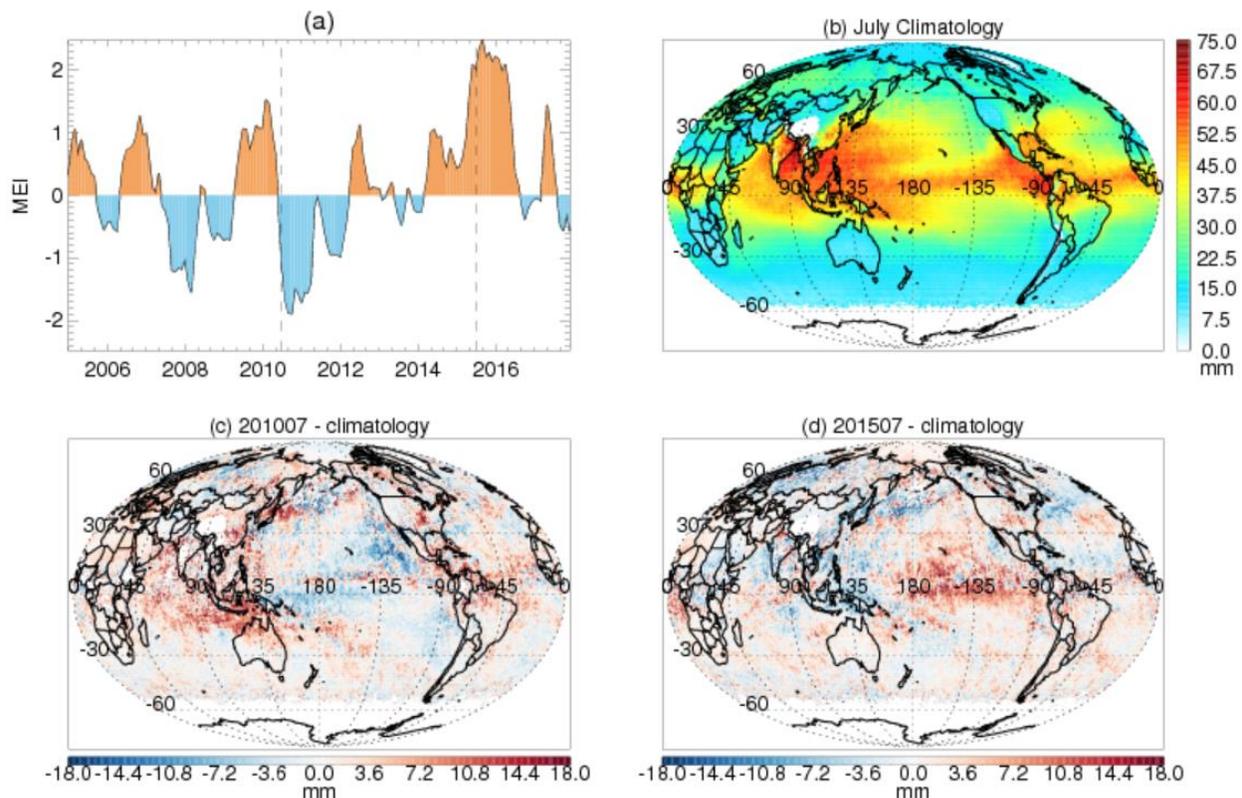

420 scatter for clouds at altitudes higher than 2.5 km where multi-layer clouds dominate (Veefkind et  
421 al., 2016). Thus, OMI TCWV data corresponding to low cloud top pressure (high altitude)  
422 should be used with caution. Relaxing the filtering criteria for both cloud fraction and cloud top  
423 pressure will lead to larger bias and scatter, therefore, it is not recommended. As an example, for  
424 cloud fraction  $< 0.15$  and cloud top pressure  $> 300$  mb, the mean (standard deviation) of OMI-  
425 SSMIS becomes 2.8 mm (9.0 mm) for July 2006.

## 426 **4 Applications**

### 427 **4.1 El Niño / La Niña**

428 In Figure 7, we examine the signals associated with El Niño and La Niña in Version 4.0 OMI  
429 TCWV. Panel (a) shows the Multivariate ENSO Index (MEI) from NOAA (Wolter and Timlin,  
430 1998) (<https://www.esrl.noaa.gov/psd/enso/mei/>). Positive (negative) values correspond to El  
431 Niño (La Niña) conditions. We examine the anomalies in TCWV for July 2010 (MEI = -1.103,  
432 La Niña) and July 2015 (MEI = 1.981, El Niño) in the bottom row. Although these events are  
433 strong within the OMI record (from 2005 to the present), they are mild in comparison with the  
434 extrema. Between 1950 and 2018, the maximum MEI is 3.008 (in March 1983) and the  
435 minimum MEI is -2.247 (in June 1955).

436

437

438 **Figure 7.** Top row: (a) Multivariate ENSO Index. Dashed vertical lines indicate July 2010 and  
 439 July 2015; (b) TCWV (mm) climatology for July derived from Version 4.0 OMI data. Bottom  
 440 row: TCWV anomaly (mm) with respect to the climatology for (c) July 2010 and (d) July 2015.

441

442 To examine the changes in OMI TCWV under different conditions, we first generate the  
 443 monthly Level 3 ( $0.5^\circ \times 0.5^\circ$ ) OMI TCWV using the Level 2 data for July 2005 and July 2015  
 444 using the method described in Section 3.2 (with a cloud fraction threshold of  $f = 0.15$  and a cloud  
 445 top pressure threshold of 750 mb). Then, using the same data filtering criteria, we derive the  
 446 climatology for July using all the Level 2 July data between 2005 and 2015 (Figure 7b). Finally,  
 447 we plot the deviations from the climatology (mm) for July 2010 and July 2015 in Figure 7(c) and  
 448 7(d), respectively.

449 The TCWV anomalies exhibit large-scale patterns. The pattern for July 2015 largely opposes  
 450 that for July 2010. Particularly, in July 2015 under El Niño conditions, TCWV are higher in the  
 451 equatorial central and eastern Pacific and lower in the Indonesia region; while in July 2010 under  
 452 La Niña conditions, TCWV are lower in the tropical eastern Pacific and equatorial western

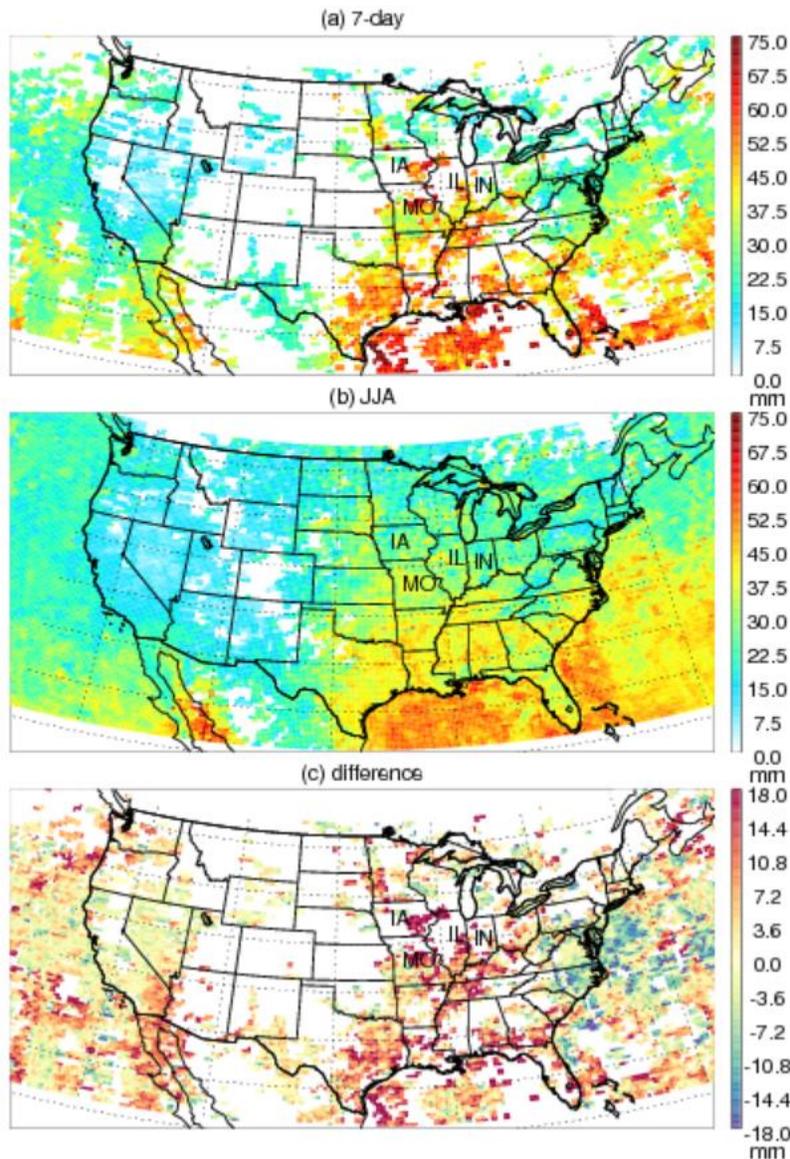

453 Pacific and higher in Indonesia and the Indian Ocean. The overall patterns largely conform to the  
454 results derived from the Hamburg Ocean Atmosphere Parameters and Fluxes from Satellite Data  
455 (HOAPS) data (Shi et al., 2018).

## 456 **4.2 Corn Sweat**

457 “Corn sweat” refers to a hot and humid condition associated with heat waves which results in  
458 large evapotranspiration rate in the Midwestern United States where cropland is often the  
459 dominant land usage type. Besides evaporation, transpiration by plants, such as corn, draws  
460 water from the soil to the atmosphere, enhancing the humidity and increasing the heat index. A  
461 corn sweat event from July 18 to July 24 in 2016 made news in the US. This event is examined  
462 in Figure 8 using the Version 4.0 OMI TCWV.

463 Figure 8 (a) and 8(b) show the Level 3 ( $0.25^{\circ} \times 0.25^{\circ}$ ) OMI TCWV for July 18 - July 24  
464 (7-day) and June 1 – August 31 (JJA) in 2016, respectively. The 7-day period corresponds to the  
465 corn sweat event. The  $0.25^{\circ} \times 0.25^{\circ}$  Level 3 data are derived using the same filtering criteria as  
466 those used for Figure 7. Figure 8(c) indicates the anomaly associated with the corn sweat event  
467 relative to the JJA mean. High TCWV is observed for the 7-day period from the Gulf coast to the  
468 Midwestern US. Besides the Gulf region, the largest TCWV enhancements (of up to 18+ mm)  
469 occur in parts of Iowa (IA), Missouri (MO), Illinois (IL) and Indiana (IN). Elevated TCWV is  
470 also observed by several GPS stations in the general area during the same time period, though  
471 coincident OMI data are not found at the stations (Supplementary Figure 3). At a few GPS  
472 stations, high TCWV persisted a couple more days after July 24 which is most likely related to a  
473 change in the weather. As shown by the surface pressure observations at the GPS stations, the  
474 Midwest is under the control of a high-pressure system during the corn sweat period and a low-  
475 pressure system afterwards (Supplementary Figure 4).

476

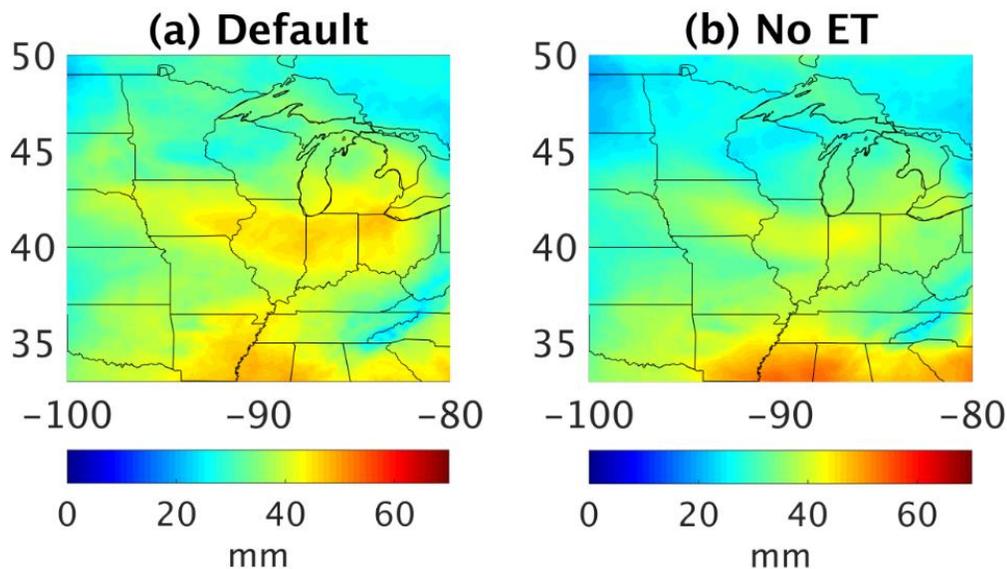

477  
 478 **Figure 8.** Level 3 ( $0.25^{\circ} \times 0.25^{\circ}$ ) OMI TCWV (mm) generated using the Level 2 data during (a)  
 479 July 18 - July 24, 2016 and (b) June 1 - August 31, 2016. (c) The difference of (a) - (b) in mm.  
 480 The abbreviations for the states most affected by the event are indicated in the map.

481  
 482 To assess the significance of evapotranspiration for the Midwestern US during the corn sweat  
 483 event, we carried out a sensitivity study using the Weather Research and Forecasting (WRF)  
 484 model v3.9.1 (Skamarock et al., 2008). The model was run on a 36-km parent domain and a 12-  
 485 km nested domain, covering the relevant areas of the US. The physics parameterizations

486 included the WRF Single-Moment (WSM) 6-Class Microphysics (Hong and Lim, 2006), the  
487 Kain-Fritsch (KF) subgrid cumulus parameterization (Kain, 2004), the Yonsei University (YSU)  
488 planetary boundary layer scheme (Hong et al., 2006), the Noah Land-Surface Model (Ek et al.,  
489 2003; Chen and Dudhia, 2001), and the Rapid Radiative Transfer Model (RRTM). Horizontal  
490 turbulent diffusion was based on the standard Smagorinsky first-order closure. The initial and  
491 lateral boundary conditions were from the 3-hourly NCEP North American Regional Reanalysis  
492 (NARR) at 32-km resolution. To reduce the uncertainty associated with lateral boundary  
493 condition for the nested domain, we nudged the model in the parent domain toward the  
494 reanalysis, but left the nested domain running freely.

495 To diagnose the contribution of evapotranspiration, the model was run from July 19<sup>th</sup> to July  
496 22<sup>nd</sup> of 2016 with and without evapotranspiration (calculated in the Noah Land-Surface model).  
497 The results for July 21<sup>st</sup> are shown in Figure 9. TCWV is generally lower in the interior of the  
498 domain for the run without evapotranspiration (No ET). The higher TCWV in the No ET run  
499 near the southern boundary reflects non-linear water vapor transport from the Gulf region.  
500 Turning off evapotranspiration not only directly affects the water vapor flux from the surface but  
501 also indirectly influences other meteorological variables, such as winds. Thus, there is a  
502 difference in the water vapor flux across the domain boundary. The difference between the  
503 default and No ET runs in Figure 9 suggests that evapotranspiration contributes about 15 – 25%  
504 of the TCWV in the Midwestern US during the corn sweat event. A detailed study incorporating  
505 TCWV data with the WRF model will be carried out in future work.

506

507 **Figure 9.** WRF simulations of TCWV (mm) for Midwestern US on 07/21/2016 for the run (a)  
508 with and (b) without evapotranspiration.

509

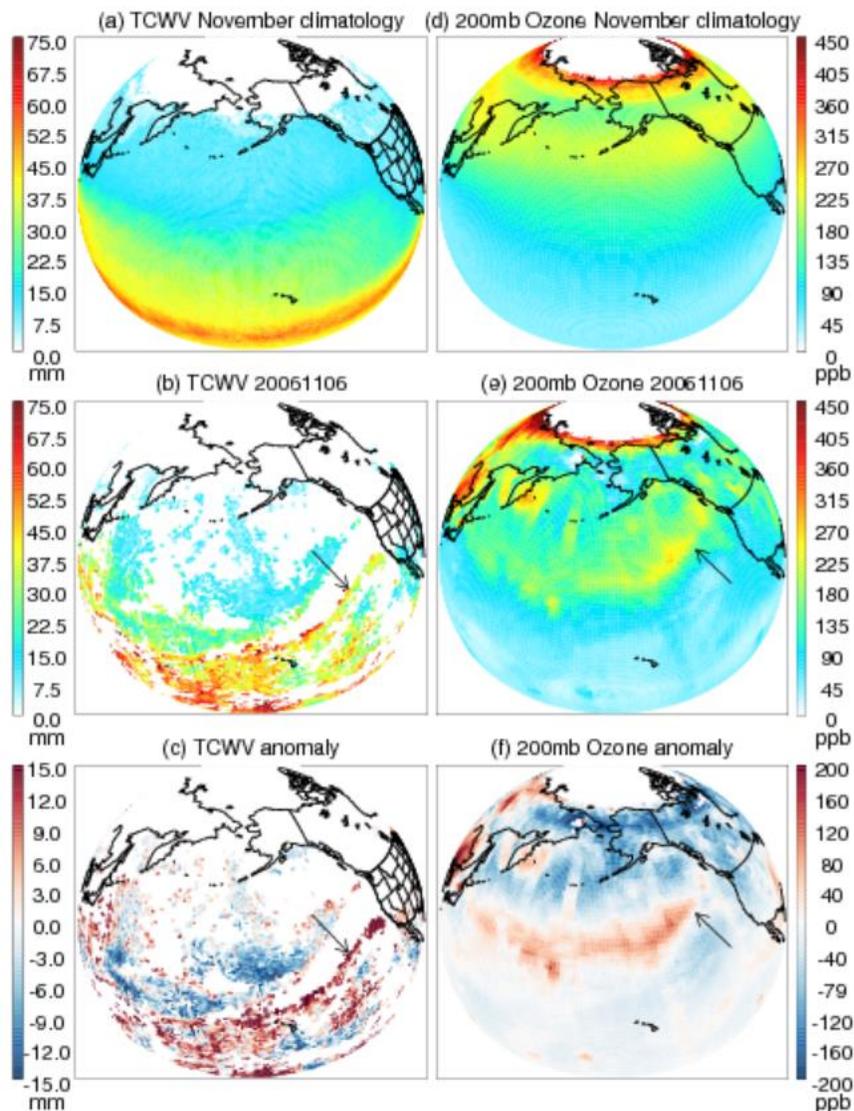

### 510 **4.3 Atmospheric River (AR)**

#### 511 **4.3.1 An Intense AR in OMI data**

512 ARs are narrow elongated bands with high TCWV in the atmosphere. With flow rates similar  
513 to those of large rivers, ARs are highly important in the global hydrological cycle (Zhu and  
514 Newell, 1998). Land-falling ARs can lead to heavy orographic precipitation that affects areas  
515 such as the west coast of North America and Europe (Gimeno et al., 2014; Neiman et al., 2008b).

516 The extreme AR of November 6<sup>th</sup> – 7<sup>th</sup>, 2006 brought devastating flood to the Pacific  
517 Northwest – the region in western North America bounded by the Pacific to the west and the  
518 Cascade mountain range to the east. This AR is described in detail in Neiman et al., 2008a. The  
519 signature of this AR is captured in the Version 4.0 OMI TCWV data. The left column of Figure  
520 10 shows the Level 3 OMI TCWV and its anomaly on November 6<sup>th</sup>, 2006. The Level 3 data are  
521 generated following the same procedure as that used for Figure 8. Although many pixels are  
522 missing because of the cloud filtering (cloud top pressure > 750 mb, cloud fraction < 0.15) and  
523 other criteria, the leading edge of the AR is noticeable as an elongated band of high TCWV (15+  
524 mm above the climatology) extending from Hawaii to Northern California (indicated by arrows  
525 in Figure 7(b) and 7(c)). The position of the AR in OMI TCWV agrees well with that in Special  
526 Sensor Microwave/Imager (SSM/I) microwave observation (Neiman et al., 2008a).

527 The right column of Figure 10 shows the Level 3 OMI ozone mixing ratio interpolated to 200  
528 mb and its anomaly. The OMI ozone data are retrieved using the SAO ozone profile algorithm  
529 (Liu et al., 2010; Huang et al., 2017, 2018). The climatology is derived by averaging all monthly  
530 Level 3 data for November from 2004 to 2017. The global distribution of ozone at 200 mb shows  
531 low mixing ratio in the low latitudes and high mixing ratio in the high latitudes, opposite to the  
532 global distribution of TCWV. The anomaly shows a curvilinear band of high ozone that is  
533 parallel to the AR in the left column, but is located further to the west. This feature indicates  
534 intrusion of ozone rich stratospheric air along the polar front, and is associated with the same  
535 extra-tropical cyclone as the AR is.

536

537 **Figure 10.** The Level 3 (top row) climatology, (middle row) data on November 6<sup>th</sup>, 2006 and  
 538 (bottom row) anomaly on November 6<sup>th</sup>, 2006 with respect to the climatology for (left column)  
 539 Version 4.0 OMI TCWV (mm, 0.5°×0.5°) and (right column) OMI ozone mixing ratio (ppb,  
 540 1°×1°) interpolated to 200 mb.

541

### 542 4.3.2 OMI TCWV Assimilation for the AR

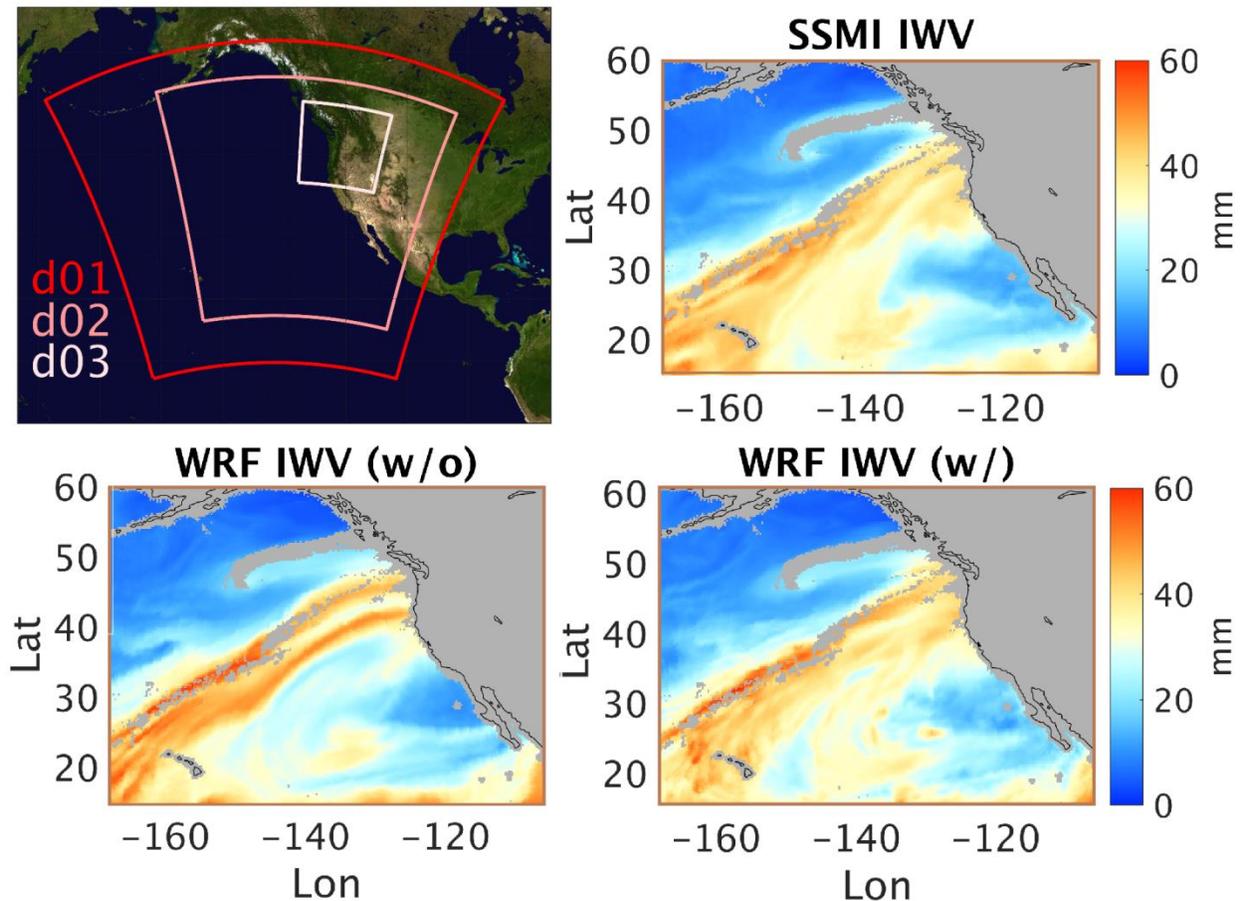

543 To evaluate the potential of OMI water vapor data to improve numerical weather forecasts,  
 544 we conducted a data assimilation experiment from November 2<sup>nd</sup> to November 8<sup>th</sup> of 2006 using  
 545 WRF v3.9.1 and Version 4.0 OMI TCWV. The model was configured with a 27-km (290×270

546 surface grid points with 51 vertical levels), a 9-km (586×586×51 points) and a 3-km  
 547 (541×526×51) nested domains in a Lambert projection over the relevant portion of the Pacific  
 548 and North America (Figure 11 top left). The domains are designed for the November 6 AR event  
 549 and its associated precipitation at landfall. The model has the same physics parameterizations as  
 550 those used in Section 4.2 except that a more sophisticated double-moment microphysics scheme  
 551 is used for quantifying precipitation. The initial and boundary conditions for the 27-km domain  
 552 were from the 1°×1° NCEP FNL reanalysis. One-way nesting is used for the inner domains. To  
 553 evaluate the model’s skill at simulating the AR and the contribution of OMI TCWV to the  
 554 quality of the simulation, we did not nudge the run towards the reanalysis, nor assimilate the  
 555 observed sea surface temperature within the computational domains.

556 The OMI TCWV is assimilated into the model using analytical optimal estimation (Rodgers,  
 557 2000). This method minimizes the cost function  $J(\mathbf{x}) = (\mathbf{y} - H\mathbf{x})^T \mathbf{E}^{-1}(\mathbf{y} - H\mathbf{x}) +$   
 558  $(\mathbf{x} - \mathbf{x}^b)^T \mathbf{B}^{-1}(\mathbf{x} - \mathbf{x}^b)$ , where  $x$  is the true TCWV,  $x^b$  is the a priori TCWV (from the model),  $y$   
 559 is the observed TCWV,  $H$  represents the model Jacobian,  $\mathbf{B}$  and  $\mathbf{E}$  are the error covariance  
 560 matrices of the a priori and observation.  $\mathbf{B}$  is estimated using the 12-hour and 24-hour forecasts  
 561 using the National Meteorological Center method (Parrish and Derber, 1992).  $\mathbf{E}$  is based on the  
 562 fitting uncertainties of OMI data.

563 The a posteriori analysis ( $\hat{\mathbf{x}}$ ) can be obtained from  $\hat{\mathbf{x}} = \mathbf{x}^b + \mathbf{K}(\mathbf{y} - H\mathbf{x})$ , where  $\mathbf{K} =$   
 564  $\mathbf{B}H^T(H\mathbf{B}H^T + W^{-1}\mathbf{E})^{-1}$  is the Kalman gain,  $W = \frac{(R^2 - r^2)}{(R^2 + r^2)}$  is the Cressman function to weigh the  
 565 observations based on their Euclidian distance  $r$  to the model grids, and  $R$  is the influence radius  
 566 of the observations. We simply assume  $R$  to be 1°, 0.5° and 0.25° for the 27-km, 9-km and 3-km  
 567 domain to get a quick look at the results in this paper and leave a more vigorous quantification of  
 568  $R$  to future work. The a posteriori TCWV is solved hourly when OMI data are available and is  
 569 used to initialize the next simulation window.

570 During the assimilation, we adjust the OMI data using the AMF calculated with the modeled  
 571 water vapor profile ( $OMI_{satellite}^{adjusted} = \frac{OMI_{satellite} \times AMF_{satellite}}{AMF_{model}}$ ) and the scattering weights provided  
 572 with the Level 2 OMI data. This can reduce the observational error associated with using the  
 573 monthly mean water vapor profile in the operational OMI product. The standard deviation of the  
 574 difference between  $AMF_{satellite}$  and  $AMF_{model}$  is about 20%.

575

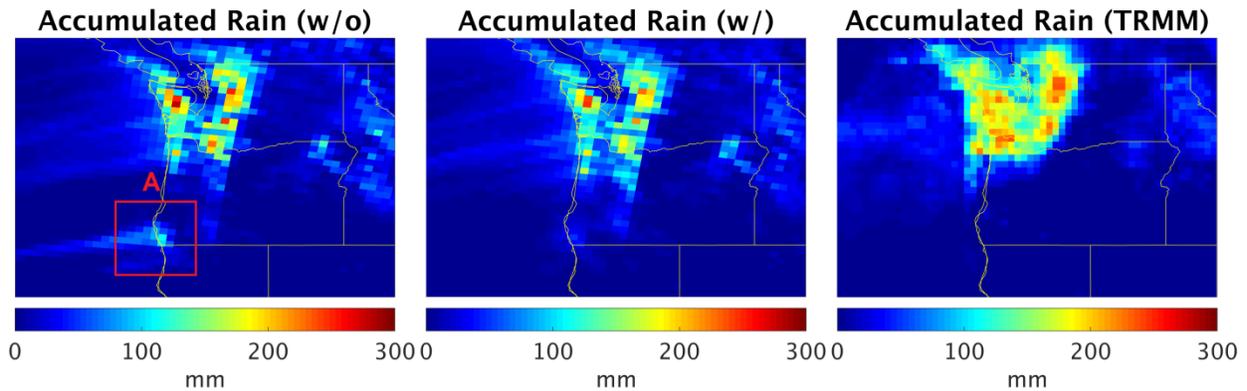

576 **Figure 11.** Top left: WRF model domain configuration for the November 2006 AR event. Top  
 577 right: TCWV observed by SSM/I on November 6<sup>th</sup>, 2006. Bottom row: TCWV simulated by  
 578 WRF on the same day (left) without and (right) with OMI TCWV data assimilation. Gray color  
 579 indicates area with no SSM/I data.

580

581 Figure 11 shows the zoomed-in views of the AR on November 6<sup>th</sup>, 2006. The TCWV  
 582 independently observed by SSM/I is shown in the upper right panel. The lower left and lower  
 583 right panels show the model results without and with OMI TCWV assimilation. The model  
 584 without assimilation shows an AR that is split into two parallel filaments making landfall at  
 585 separate locations on the west coast of North America, where the TCWV is too high compared to  
 586 the SSM/I observation, especially for the southern filament. As discussed later, this has a  
 587 significant impact on precipitation (Figure 12). After assimilating OMI TCWV, the modeled

588 TCWV agrees much better with the SSM/I observation. The spurious southern filament  
589 disappeared, the overall shape and amplitude of the AR are significantly improved.

590 The location and intensity of precipitation over land are crucial for local flood control and  
591 water resource management, and are closely related to the shape and strength of AR at landfall.  
592 The 24-hour accumulated precipitation on November 6 in the 3-km domain is examined in  
593 Figure 12. The model output is coarsened to  $0.25^\circ \times 0.25^\circ$  to match the resolution of the Tropical  
594 Rainfall Measuring Mission (TRMM) observation product. The model without OMI data  
595 assimilation produces spurious rainfall over the Oregon - California border (box A) as a result of  
596 the erroneously strong southern filament of the simulated AR (Figure 11, lower left panel). This  
597 artifact was removed after OMI data assimilation, showing better agreement with the  
598 corresponding TRMM rainfall observation. The difference in rainfall between the assimilation  
599 and observation in the Oregon / Washington area is probably related to both the model error and  
600 the data error, as well as the data density and distribution. A detailed error attribution for  
601 precipitation is beyond the scope of this paper.

602  
603 **Figure 12.** The simulated rainfall accumulated from 0000 UTC to 2300 UTC (in mm) on  
604 November 6, 2006 for the model (left) without and (middle) with OMI TCWV assimilation. The  
605 rightmost panel show the accumulated rainfall observed by TRMM for the same time period.  
606 Note that the 3-km model result is coarsened to match the resolution of the TRMM product.  
607 Box A highlights the erroneously simulated precipitation in the run without OMI TCWV data  
608 assimilation.

609

## 610 5 Summary and Conclusion

611 The Version 4.0 retrieval algorithm for OMI Total Column Water Vapor (TCWV) is presented  
612 in this paper. The algorithm follows the usual two-step approach where Slant Column Density  
613 (SCD) is derived from spectral fitting and Vertical Column Density (VCD) is obtained through  
614 the ratio of SCD and Air Mass Factor (AMF). In Version 4.0, the spectral fitting no longer  
615 considers common mode. The retrieval window (432.0 - 466.5 nm) results from a systematic  
616 optimization that reflects trade-offs among several factors, including small fitting RMS, small  
617 fitting uncertainty, large fraction of successful retrieval and long retrieval window length. The  
618 AMF calculation uses the latest OMI O<sub>2</sub>-O<sub>2</sub> cloud product (Veefkind et al., 2016) and monthly  
619 variable vertical profiles from the MERRA-2 reanalysis (Gelaro et al., 2017).

620 The Version 4.0 OMI TCWV product is compared against the GPS network data over land  
621 and the SSMIS microwave observations over the oceans for 2006. Version 4.0 OMI TCWV has  
622 much smaller bias than Version 3.0 and has replaced previous versions on the Aura Validation  
623 Data Center website. Version 4.0 OMI TCWV is characterized under different cloud conditions.  
624 Under “clear-sky” condition (cloud fraction < 5% and cloud top pressure > 750 mb), the overall  
625 mean of OMI-GPS over land is 0.32 mm with a standard deviation of 5.2 mm, and the smallest  
626 bias occurs when TCWV is between 10 mm and 20 mm; the overall mean of OMI-SSMIS over  
627 the oceans is 0.4 – 1.1 mm with a standard deviation of 6.5 - 6.8 mm, and the smallest bias  
628 occurs for TCWV between 20 mm and 30 mm. The correlation coefficient between OMI TCWV  
629 and the reference datasets realizes the largest gain when the cloud fraction threshold is increased  
630 from 5% to 15%. The regression line appears the best when  $f = 0.25$  is used over land and when  $f$   
631  $= 0.15$  is used over the oceans. But, larger cloud fraction leads to larger bias and scatter. Thus,  
632 for most applications, we recommend to consider only OMI data with cloud fraction < 5% to  
633 25% and cloud top pressure > 750 mb, in addition to main data quality flag = 0, no row anomaly,  
634 fitting RMS < 0.001 and  $0 < \text{TCWV} < 75$  mm. Relaxing the cloud top pressure threshold has a  
635 similar effect as relaxing the cloud fraction threshold. TCWV corresponding to low cloud top  
636 pressure (high altitude) should be used with caution due to the degraded accuracy for these  
637 clouds in the OMCLDO2 product.

638 As example applications of the Version 4.0 OMI TCWV data across a variety of temporal  
639 and spatial scales, this paper examines the climate pattern associated with El Niño / La Niña, the  
640 enhanced humidity during a week-long corn sweat event in the Midwest US, and the linear band  
641 of high TCWV associated with an intense atmospheric river which made landfall on the west

642 coast of North America. Strong signals are found in OMI TCWV for all three examples. A data  
643 assimilation experiment shows that the OMI TCWV data can help improve WRF's skill of  
644 simulating the shape and intensity of the AR, as well as the accumulated rainfall near the coast.

645 Further improvement of the product can proceed from both spectral fitting and AMF  
646 calculation, such as, water vapor reference spectrum, instrument slit-function and solar irradiance  
647 for spectral fitting, aerosol correction and surface bi-directional reflectance for AMF calculation.

648

#### 649 **Data availability**

650 The GPS network data are downloaded from NCAR ([rda.ucar.edu/datasets/ds721.1](http://rda.ucar.edu/datasets/ds721.1)). The SSMIS  
651 data used in this paper are downloaded from the Remote Sensing Systems  
652 (<http://www.remss.com/support/data-shortcut/>). The Multivariate ENSO Indices are downloaded  
653 from NOAA (<https://www.esrl.noaa.gov/psd/enso/mei/table.html>). OMI TCWV and ozone  
654 profile data are released through the Aura Validation Data Center (<https://avdc.gsfc.nasa.gov/>).

655

#### 656 **Author contribution**

657 Huiqun Wang optimized the OMI TCWV retrieval window, performed the data validation  
658 and tested most of the data application described in this paper. Amir Souri performed the WRF  
659 simulations and data assimilation experiment presented in this paper. Gonzalo González Abad  
660 improved and maintained the SAO retrieval code and implemented OMI TCWV data production  
661 for the Aura Validation Data Center. Xiong Liu developed the OMI ozone profile retrieval and  
662 provided the relevant data used in the AR application. Kelly Chance is the PI of the NASA grant,  
663 and is responsible for the overall direction and execution of the project. Huiqun Wang prepared  
664 and revised the manuscript with contributions from all co-authors. All authors contributed to  
665 technical and scientific discussions during this project.

666

#### 667 **Competing interests**

668 The authors declare that they have no conflict of interest.

669

670 **Acknowledgement**

671 We thank NASA's ACMAP program (Grant NNX17AH47G) for support.
